and fruits particularly banana. The total area under five crop combinations of 12.81sq. km constitutes 2.64 per cent of the total area of the taluk in both the time period. The application of Weaver's methods shows the realistic picture of crop combination. Three Crop Combination regions have found rice with a study area. Monoculture is in one village out of five villages in our study area. Two crop combinations are found in eleven villages. Three crop combinations are found in twenty villages in the study area .Four crop combinations are found in four villages in the study area. Five crop combinations are found in one village in the study area.

Crop Diversification

The whole study area is divided into three type of crop diversification regions, identified as (a) High crop diversification area, (b) Moderate crop diversification area and (c) Low crop diversification area (Fig. 1). The high Crop diversification is observed in 23 Villages of the study area. Majority of villages are in Nilakottai block they are Kolladipatty (0.71), Nilakottai (0.75) Kullalakundu (0.71), Pachamalayankottai (0.61), in southern side of Nilakottai block, Kottur (0.62), Ethilode (0.63), Pillaiyarnatham (0.65), Jambuduraikottai (0.65), Pallapatti (0.66), Bodiakoundenpatti (0.66), Silukkuvarpatty (0.66) in eastern part of the Nilakottai block, and the remaining five villages situated in south and south eastern side of Nilakottai block at Kulli Chettipatti (0.67), Koovanuthu(0.67), Malaiyakoundenpatti (0.68), Kompaipatti (0.68), Nariyuthu (0.69), Sivagnanapuram (0.69), Chinnamanaickankottai (0.70) and the Batlagundu block villages at eastern side of the study area in Rengappanaickanpatti (0.70), Mallanampatty (0.71), Kuruvankottai (0.64), Bangalapatti (0.66), Chandaiyur (0.60) ,Moderate Crop Diversification is found in 17 villages of both block, in that Nilakottai block only eleven villages identified in eastern side of Nilakottai block of Mattaparai (0.60), Vilampatti (0.42), Viralimayanpatti (0.42), Kanavaipatty (0.46), Nuthulapuram (0.47), Oruthattu (0.51), Sithargal natham (0.52),Veelinaickanpatti (0.53), Kodenginaickenpatti (0.53), Musuvanuthu (0.55), Viruveedu (0.58) in Nilakottai block south and south western side of cultivable land, remaining six villages were observed in Batlagundu block villages of Batlagundu (0.56), Viralipatti (0.57), Pannaipatty (0.58), in eastern side and Senkattanpatti (0.58), Nadakottai (0.59), Sevugampatty (0.59), in northern side of Batlagundu block, Ramarajapuram (0.09), Sekkapatti (0.32), Nakkaluthu (0.37) in southern side of Nilakottai block were observed low crop diversification region during the period. During the year 2017-18, the maximum crop diversification appears in Nadakottai (0.77) village of Batlagundu block, and the lowest crop diversification also identified in (Batlagundu block), where it is Senkattanpatti

(0.06) village. The region under high crop diversification is observed in 17 villages, Oruthattu (0.61), Kullalakundu (0.61), Sivagnanapuram (0.61), Veelinaickanpatti (0.61), Musuvanuthu (0.64), Ethilode (0.64), Bodiakoundenpatti (0.65), Pallapatti (0.66) Kompaipatti (0.69) and Bangalapatti (0.67) all these villages located at the south and south eastern part of the Nilakottai block. Pannaipatty (0.65), Batlagundu (0.66), Mallanampatty (0.70), Chandaiyur (0.71), Rengappanaickanpatti (0.72), Viruveedu (0.73) and Sekkapatti (0.74) villages are located in east and central part of the study area in Batlagundu block.

Moderate crop diversification is noted in 16 villages of Kolladipatty (0.43), Nakkaluthu (0.45), Chinnamanaickankottai (0.47), Silukkuvarpatty (0.52), Kottur (0.52), Nuthulapuram (0.52), Kullichettipatty (0.53), Nilakottai (0.53), Pillyarnatham (0.54), Mattaparai (0.54), Kodenginaickenpatti (0.56), Koovanuthu (0.56), Malaiyakoundenpatti (0.58), Sithargal Natham (0.59) and Nariyuthu (0.59) in all direction of the study area in Nilakottai block. Viralipatti (0.60) and Sevugampatty (0.60) are the two villages found in Batlagundu block that are noted as moderate crop diversification. The low crop diversification is observed four villages of Nilakottai blocks, it have identified in south and western part of Vilampatti (0.38), Ramarajapuram (0.38), Jambuduraikottai, Pachamalayankottai (0.28) and Senkattanpatti (0.06), Kunruvarankottai (0.08), Viralimayanpatti (0.17) and Kanavaipatty (0.34) in north and north eastern part of Batlagundu blocks (Fig No.3.19).

Conclusion

When comparing the temporal years 2018 and 2008, Spatial and temporal distribution crop indicates that increase in area under cultivation is noted These cereals, spices, sugar crops, oil seeds cultivation are higher in Nilakottai block than Bathlagundu block. Mean while decrease is also maximum in Batlagundu block compared to Nilakottai block, the decrease is noted in 22 villages mainly spread in the Nilakottai blocks than Batlagundu block the increase in flower cultivation is noticed in 23 villages spread spatially high in Nilakottai block compared to Batlagundu block. . Monoculture is in one village out of five villages in our study area. Two crop combinations are found in eleven villages. Three crop combinations are found in twenty villages in the study area. Four crop combinations are found in four villages in the study area. Five crop combinations are found in one village in the study area. The availability of irrigation facilities and the soil favoured more crop cultivation in this region. Crop diversification clearly denotes the low crop diversification area is decreased and high crop diversification is increased during

2017-18 especially in Nilakottai block in eastern side of the taluk than Bathalagundu block it clearly brought out that the cropping pattern, crop combination, crop diversification of the study area is highly influenced by the physical and socio-economic factors of the taluk.

EXAMINING STATE'S ELECTORAL POLITICS THROUGH THE REGIONAL EYE- A CASE STUDY OF AHIRWAL REGION IN HARYANA

Dr. Sachinder Singh

Abstract

In Indian federal union, different states act as separate political arenas for both political parties and voters. For political parties these are the electoral battlegrounds to contest for gaining the seat of power and for the voters to make their choices felt in the elections either held for the parliament or state assemblies or local bodies. However, over the period of time, it is also being felt that state in itself is not a homogeneous unit for analyzing the electoral contests. States also constitute different regions, each come up with its own unique genesis and preference in favour of or against a political party. The bonds of liking or disliking for a particular party by majority of the voters of a region may remain stable or change with the passage of time. In the present research paper the above stated proposition is tested by taking a case study of Haryana wherein the electoral analysis was done at two levels, i.e. Haryana state and the Ahirwal region of Haryana. For analyzing the fact whether the Ahirwal region vote in favour/against a political party en masse and whether the voters in the region go as per the general trends in the state, the electoral analysis of two political parties in the last three assembly elections (2009, 2014, 2019) in Haryana vis-à-vis the Ahirwal region was done. The electoral performances of the selected parties were measured in terms of percent vote polled, and seats won in the selected elections.

Introduction

The Indian federal democratic structure permits electoral analysis to be carried out at various levels, viz., national, state and local. Although one can analyze the patterns of electoral politics independently on any of these levels or a combination of these levels, however, the fact remains is that the politics is being constructed as a consequence of innumerable events working in combination to each other from national to local level. To simplify the fact, the national politics (i.e. politics viewed at the national level) is not something which is being constructed at that level only;

rather it is an assemblage of politics constructed at various geographical levels. This argument, however, does not mean to underestimate the national level political happenings that play their own role in the making of national politics. In terms of electoral analysis in India, it was the analysis of electoral politics at the national level that was given pre-eminence for quite a long time, especially the decades that followed the independence. During the phase of the Congress System (i.e., the period when the Congress was at the centre of all levels of politics and the regional voices were subtle) even studies carried out at the state level were looked at from the national perspective (Yadav and Palshikar, 2003). This viewpoint had changed to some extent after the 1967 State Assembly elections, when in many states, non-Congress governments were formed. With this, the era of unchallenged supremacy of the Congress came to an end. This political change had led to advancement of the idea that state specific politics is different from the national politics. With this consideration, state specific election studies became important. Henceforth, various important state specific election studies were carried out and published (Weiner, 1968; Narain, 1976; Jenkins, 2004). In fact, as we scale down our analysis of understanding the Indian politics from the national level, we find construction of politics at varied scales. If we view politics at the level of state, each state emerges with its own distinct patterns of politics that is going on therein at a moment of time.

However, close analysis will further show that even state politics is not homogeneous in itself. Each state consists of various regions of unique political identities formed in the name of caste, language, religion etc. Recently we are witnessing this shift in electoral studies from national/state level to the study about construction and analysis of electoral politics at the level of region. This changeover came with the realization that states constitute different regions, each with its own unique genesis and preference about a political party. The way majority of the voters of a region vote in favour or against a political party may remain stable or change with the passage of time. The focus on study of electoral politics at the level of region is in tune with unique voices emerging from different social-cultural regions of the country, i.e. the emergence of identity politics. Historically, in some parts of the country these regional voices were so strong that had even led to the creation of separate states and many of such demands are still keeping alive. In fact, the "process by which subaltern groups have politicized has varied enormously from state to state" (Jenkins, 2004:2). In a large federal country like India, this construction of politics at the level of region takes place some way in-between the national/state politics on the one hand and locality politics on the other. It retains the characteristics of both higher and lower levels of politics without losing the regional identity.

This construction of politics at the level of region is unique in the sense that a region is constructed and re-constructed in social-political-economic terms in a time framework. It is a very slow and gradual process of developing a unique culture of politics. The regional identity may be dormant or active in political terms. It depends on the aspirations and participation of people living therein. How politics is being constructed and re-constructed at the unit of region is always going to be an imperative exercise for unraveling the complex nature of national and state level politics in India. However, despite having so much unique regional electoral politics in the country "there has been a dearth of literature that focuses on the region within states…" (Kumar, 2011:11). This is despite being the fact that cultural heterogeneity of the regions within states over the years has been sharpened as a result of unevenness of development and unequal access to political power (Sathyamurthy, 2000:33). The proposed study intends to fill this academic gap, especially by taking a case study from the state of Haryana. Despite being a small state in terms of geographical area, Haryana has its own socio-cultural regional framework wherein certain castes and religious groups are dominant and have their say in the electoral contests. One such socio-cultural region is the Ahirwal region of Haryana which was in news for having an important say in the formation of the BJP government in the state in 2019. There is hardly any study in terms of analyzing the electoral politics of the region. Yadav (2000) had discussed about the Ahirwal region in historical perspective. Similarly Yadav (2003) has briefly discussed about the Ahirwal region in his study on the social coalitions and power strategies made by different political parties to capture power in the state

Study Region

Despite Haryana being a small state in terms of geographical area, there are various specific regions where different religious/caste groups (Sikhs, Muslims, Jats, Ahirs etc.) dominate in terms of their numerical strength. One of such regions is the Ahirwal or the 'Land of the Ahirs'. Broadly it is a region which lies in both Haryana (southern parts) and neighbouring state of Rajasthan (north-eastern parts). It was described at length by Joseph E. Schwartzberg in his study of Folk Regions of Northwestern India as a 'folk region' (Schwartzberg, 1978, 1985). The history and culture of this region is mentioned in an exclusive study by K.C. Yadav (Yadav, 2000). It was also mentioned by Lucia Michelutti in her study as a 'cultural-geographical region' (Michelutti, 2008: 42). Broadly the region includes the districts of Alwar and Bharatpur in Rajasthan, and districts of Mahendragarh, Rewari and Gurgaon in the state of Haryana. In the present study,

Ahirwal region of Haryana only is undertaken for the study. It was on two accounts. One, assembly elections in the two states were held at different dates, and two, the issues that had emerged and affected the voters' preferences were different. Ahirs are commonly known with different names such as Hir, Yadav, Rao ji, Rao Sahib. In Haryana their area of concentration is known as Ahirwal region. Although Ahirs are one of the backward castes in the state but "they have the self-perception of being a Kshatirya upper caste" (Yadav, 2003:147). There are "three main categories among the Ahirs of Haryana and the neighbouring states" (Sangwan, 1994:14). These are Afaria Ahirs, Gwala Ahirs, and the peasants. The Afaria Ahirs belong to the category of big landlords and used to live in small fort like structures. They consider themselves as Rao Sahib and their fort like structures in Haryana are found in villages like "Kila Pathani, Ahi Bharwi, Tirpur and Jaitpur near Rewari…" (Sangwan, 1994:13). Gwala Ahirs are those whose main occupation is that of rearing of animals and related activities. The third category belongs to peasants who are in large number. Over the period of time, although this class division among the Ahirs has narrowed down but not diminished. In Haryana, the Ahirwal region has 11 assembly constituencies. Such a spatial concentration of a particular caste in a state assists the people in creating and retaining a kind of separate identity.

Till recently, the nature of electoral contests in the region largely remained between the Indian National Congress (the Congress) and the Indian National Lok Dal (INLD). However, the dramatic success of the Bharatiya Janata Party (BJP) in the last two assembly elections has changed the political scenario of the state and that of the region as well. Whereas, the BJP had failed to win any of the eleven assembly constituencies in the region in 2009 assembly elections, it won all the eleven assembly seats in 2014 elections. In 2019 assembly elections, when there was decline in the total number of seats won by the BJP in the state (47 in 2014 to 40 in 2019), it managed to retain eight seats (out of eleven) in the region. This was despite being the fact that the electoral scenario for the party was different in surrounding socio-cultural regions of the state in 2019 assembly elections. The party could win one (i.e. Hathin) of the four Meo-Muslims dominated seats of Nuh, Ferozepur Jhirka, Punhana, and Hathin. Similarly in the 14 assembly constituencies of the neighbouring districts of Bhiwani, Rohtak and Jhajjar (a part of the Jatland) the party seats tally declined from six in 2014 to three in 2019. The eight assembly seats that the party had won from the Ahirwal region were one of the main determining factors that the BJP was able to form the government in the state in 2019.

Objectives

(1) The electoral performance of selected political parties in Haryana state in general and Ahirwal region in particular; and,
(2) The impact of switching over of Rao Inderjit Singh on February 13, 2014 from the Congress to the BJP in Ahirwal region in general and Kosli assembly segment of the Rohtak Lok Sabha in particular.

Database and Methodology

For analyzing the electoral dynamics in Haryana state in general and Ahirwal region in particular, assembly constituency wise data for the last three assembly elections of 2009, 2014, and 2019 were taken. These elections were held as per the Delimitation Order of Constituencies, 2008. In the study, special focus is on the eleven assembly constituencies of the Ahirwal region: Ateli (68), Mahendragarh (69), Narnaul (70), Nangal Chaudhary (71) of district Mahendragarh; Bawal (SC) (72), Kosli (73), Rewari (74) of district Rewari; Pataudi (SC) (75), Badshahpur (76), Gurgaon (77) and Sohna (78) of Gurgaon district (Fig. 1). The assembly constituencies of Ateli, Mahendragarh, Narnaul and Nangal Chaudhary are part of the Lok Sabha seat of Bhiwani-Mahendragarh; and Bawal (SC), Rewari, Pataudi (SC), Badshahpur, Gurgaon and Sohna are part of Gurgaon Lok Sabh seat. Kosli is one of the assembly segments of Rohtak Lok Sabha seat .Two national parties, viz. the Congress and the BJP were chosen for the analysis. The justification behind selecting these two political parties was twofold. One, these were the only political parties which had contested all the ninety assembly seats in the state during the three elections taken for the analysis. Two, the contest for gaining the seat of power basically remained between these two political parties. The Congress formed the government after 2009 assembly elections, whereas, the BJP formed the government after the 2014 assembly elections and also after the 2019 assembly elections. The electoral performances of both the parties were measured in terms of percent vote polled, average vote, seats won and co-efficient of variation (CV). Assembly constituency wise data were taken from the reports published by the Election Commission of India.

Result and Discussion

Historical background of politics in Ahirwal region

To begin with, the politics in the region was divided among the followers of three political parties, viz. the Congress, the Unionist Party, and the Punjab Hindu

Mahasabha. The real contest, however, was between the latter two. In electoral terms, the Congress was comparatively stronger in the urban areas. The Unionist Party, on the other hand, was comparatively more popular in rural areas. It was led by Sir Chhotu Ram and Sir Fazl-i-Husain (for details see, Wallace, 1980; Chowdhry, 1991). Although Chhotu Ram "began his political career as a congressman but soon discovered that this organization had no agrarian programme worth the name and secondly it was dominated by the well-to-do urbanites who flourished on the exploitation of peasantry" (Choudhry, 1985:120). For the welfare of peasants he, along with Fazl-i-Husain had formed the Unionist Party and was able to enact various agrarian laws in their favour. This had, however, further deepened the rift between the urban and rural elites. This social rift started emerging during the Non-Cooperation Movement (1923). In fact, the "rural agriculturalist elite was not prepared to cooperate with the urban elite on the issue of non-payment of land revenue as they considered it very harmful to the interests of agriculturalists" (Singh, 1977: 65). At that time, the main contest for gaining the seat of power in the region was between the Punjab Hindu Mahasabha and the Unionist Party.

The prominent political leaders were Rao Balbir Singh (from Punjab Hindu Mahasabha), and Rao Pohap Singh and Rao Mohar Singh (from the Unionist Party). Presently, the political legacies of Rao Balbir Singh and Rao Mohar Singh are popularly known as Rampura House and Budhpur House. In addition to these two Houses, the Captain House has its own importance in the region's politics. The nomenclatures of these houses are based on either the family name or on the basis of ancestral villages of these political families. Members of these houses have remained at the helm of affairs in various governments formed by different political parties in the state as well as in the central government. However, there remains a sort of political rivalry between these houses for gaining more and more political space of the region. It is also important here to mention that of the persons representing these houses, many have changed their alignments with different political parties. The death of Sir Chhotu Ram on January 9, 1945 was disastrous for the Unionist Party. The number of seats won by the party in the British Punjab came down from 98 seats (out of total 175) in 1937 to 11 seats in 1946. The Congress on the other hand, improved its seats tally from 18 seats to 51 seats during the same time period. The Ahirwal region also went for this change. The Ahirs also shifted their alliance to the Congress as it was expected that once independence is achieved, it would be the Congress led government in India. An overview of the three Houses around which politics in the region revolves is as under:

Rampura House

The politics in the region is influenced by the family members of Rao Tula Ram, the hero of the revolt of 1857. Rao Balbir Singh, a descendant of Rao Tula Ram, was founder of Rampura House. He was the Head of the Election Board of the Hindu Mahasabha for the Punjab Legislative Assembly (see, Yadav, 2002:185). He was "the first Ahir to contest election to the provincial legislative council in 1916 against Ch. Lal Chand. The Ahirs solidly backed Balbir Singh…but being in a minority they failed in getting Balbir Singh elected" (Yadav, 1980:9). However, things changed after the introduction of the Montague Chelmsford reforms of 1919 under which the right to franchise was liberalized and constituencies were delimited separately as urban and rural. Now the chances of winning an Ahir candidate from a rural constituency got enhanced as Ahirs were mainly rural. And when the first election after these reforms was held in 1920, Rao Balbir Singh was elected to the Council from Gurgaon (Non-Mohammedan) Rural seat. He was colleague of Rao Mohar Singh (of Budhpur House) in the Punjab Legislative Council. Rao Balbir Singh remained member of the Punjab Legislative Council and Punjab Legislative Assembly on many occasions in the United Punjab from 1921 to 1941. In the mid, he was defeated by Rao Pohap Singh (a young lawyer and a big landlord) of the Unionist Party in 1923.

He, however, came back in 1926 and 1930 elections on the Hindu Mahasabha Ticket. He was elected again in 1937 from the same seat. The Unionist Party led by Sir Chhotu Ram could recover the lost ground in the region only after the death of Balbir Singh in 1941. Rao Balbir Singh was also instrumental in establishing Ahir Yadav Kshtirya Mahasabha in Rewari as early as 1910. After his death, it was in 1945 that Rani Nihal Kaur (wife of Rao Balbir Singh) had adopted Rao Birender Singh as Head of the Rampura House. Rao Birender Singh, a graduate from St. Stephen College, Delhi, was enrolled in the Territorial Army during the World War II. In 1947 he resigned from the Army as a Captain and returned back to Rampura. He established various educational institutions: Ahir College, Rewari; R.B.S. School, Rewari; Rao Tularam School, Rewari; Rao Tularam Technical College, Delhi; R.B.S. College of Education, Rampura. He became a member of the legislative council in 1954 and was a minister in the Punjab government. After the formation of Haryana as a separate state in 1966, he became the first speaker of the Haryana State Assembly. Owing to his differences with first Chief Minister of Haryana (Bhagwat Dayal Sharma) he left the Congress which ultimately led to fall of the government. He was instrumental in forming Samyukta Vidhayak Dal (SVD)

and became second Chief Minister of the state (March 24 to Nov. 2, 1967). After dissolving SVD, he formed his own political party as Vishal Haryana Party (VHP, first regional political party of Haryana) in 1967 (Singh, 1971). The party was, however, merged with the Congress (I) on September 23, 1978. "The Ahirs have mostly been voting for the Congress (I) after the merger…" (Singh, 2003:353). Thereafter he played his role in the central politics as a Member of Parliament on a few occasions. In 1989 he left the Congress and joined Janata Dal. He remained president of All India Yadav Mahasabha many a times. Another important personality of the House was great granddaughter of Rao Tula Ram, the then ruler of Rewari, and daughter of Rao Balbir Singh, Rajkumari Sumitra Dev (Bai Ji as popularly known). A Padma Shri awardee in 1968, she is still known for her untiring efforts for social service and especially for upliftment of women and children, and animal protection. She was President, District Congress Committee, and Vice President of Punjab Congress Committee (for details see, Government of Punjab, 1964:104). She was elected unopposed to the second Punjab Vidhan Sabha on the Congress ticket in 1957 from Rewari assembly constituency. In 1962 and 1967 she was re-elected from Rewari assembly seat as a Congress party candidate by huge winning margin of 33.81 and 16.27 percent vote respectively. In 1968, she contested the Rewari seat on VHP seat and won by a margin of 10.76 percent vote. For devoting all her time for the social cause, she remained unmarried. After the death of Rao Birender Singh, his political legacy was continued by his son, Rao Inderjit Singh, a product of Lawrence School, Sanawar and Delhi University. Like his father he has played his role both in the state and central politics as minister of different portfolios.

On September 23, 2013 he gave his decision of quitting the Congress and floated a non-political outfit Haryana Insaf Manch. His daughter Arti Singh Rao was also associated with this non-political outfit. The formation of this Manch was an attempt to raise the issues related to discrimination in development in the state. It was alleged that Bhupinder Singh Hooda led Congress government had favoured the districts of Rohtak, Jhajjar and Sonepat at the cost of other districts and there was discrimination in canal water allocation. He also stated that farmer's land was acquired forcefully by the state government and people were avoided in employment opportunities and development projects. On 13 February, 2014 in the presence of BJP National President, Sh. Rajnath Singh, he joined the BJP on the Martyrdom Day of Rao Tularam. He became a Member of Parliament on BJP ticket from Gurgaon parliamentary constituency.

Rao Inderjit Singh's two brothers (Rao Yadavendra and Rao Ajit Singh) and his daughter Arti Rao are also actively playing their role in the politics of the region. Although, Rampura House is now a divided house, as many of the extended members of the family are in different political parties, but Rao Inderjit Singh is the most important face of the house. It would be interesting to analyse the impact on voters of Rao Inderjit Singh quitting the Congress and joining the BJP. This is especially in regard to his public statement on April 3, 2014 that 'I know that people love me and not the flag I carry'. Interestingly Rao Inderjit Sigh joined the party he kept on criticizing for more than three decades. The impact of Rao Indejit Singh joining the BJP would be of special interest in the case of the electoral performance in the Kosli assembly constituency. Here it is important to mention that the Kosli assembly constituency is a part of the Ahirwal region of Haryana but if falls in the Rohtak parliamentary seat. Rao Inderjit Singh remained member of legislative assembly from Jatusana seat four times (1977, 1982, 1991, 2000).

Budhpur House

The Budhpur House was founded by Rao Mohar Singh (born in July 1903 in Budhpur village). His father, Rao Ramji Lal was the first person from Gurgaon district who cleared the Punjab Civil Services and became administrator of Nalagarh state during the British times. Rao Mohar Singh did his graduation from St. Stephen College, Delhi, and education of law from Lahore Law College in 1930. It was during his practicing day in Gurgaon that he came in close contact of Rao Pohap Singh and joined the Unionist Party (popularly known as Zamindara Party). However, it was only after the death of Rao Balbir Singh in 1941 that the Unionist Party could break the dominance of Punjab Hindu Mahasabha. Its candidate, Rao Mohar Singh won the North West Gurgaon General Rural seat in the by-election held in 1941 (due to death of Rao Balbir Singh). He won again in 1946 by defeating Rao Gajraj Singh (a member of Rao Balbir Singh's family). His son Rao Mahabir Singh was elected member of legislative assembly on three times and was minister in the state. He also contributed in the field of education by establishing Kamla Nehru College, Jatauli, and Rao Mohar Singh College of Education, Behrampur. The grandson of Rao Mohar Singh, Rao Narbir Singh is also in the field of politics and remained minister in the state government. Narbir Singh had defeated Rao Inderjit Singh from Jatusana assembly constituency in his debut election of 1987. In his turn, however, Inderjit Singh defeated Narbir Singh in 2009 Lok Sabha election from Gurgaon.

Captain House

To begin with, Rao Abhay Singh who became MLA three times was head of this house. However, this house is known after Captain Ajay Yadav, son of Rao Abhay Singh. Before joining politics, Ajay Yadav served the Indian Army as a Captain. He is playing a very important role in the politics of the region. It needs to mention here that he was elected on the Rewari assembly constituency consecutively for six times and that shows his popularity. Now his son, Chiranjeev Rao who is MLA from Rewari is leading his legacy. Among the three houses, the Rampura House is certainly the most important in terms of influencing the choices of voters in the region and there are certain reasons for that: one, this house belongs to the legacy of Rao Tula Ram and that legacy still works in the region. Two, this house had played an important role in the process of recruitment of local youth during the World War-I. In fact, this region belonged to arid/semi-arid climatic conditions with limited agricultural opportunities at least to begin with. In that scenario, the World War-I brought about a big change in improving the socio-economic conditions of the people here. The enrolment of local youth in the armed forces not only provided employment opportunities but also acted as a gateway to occupational mobility and modern world exposure. This had also awakened them as social and political being. At that time "Rao Balbir Singh, the second descendant of Rao Tula Ram acted as a recruiting agent of the British Government, and since then many Ahirs have joined the Army in increasing numbers" (Rao, 1964:1440). This had created a linkage of local people with this House. Even the big landlords were in favour of the British as they took the event as a means of future rewards. Three, many members of this house have remained on top positions both in the state and central governments. Four, the establishment of various educational and other social welfare institutions by the representative of this house have had worked at the grass root level in strengthening the people's bond with the house. Five, constant rise of voice by the representatives of this house at various platforms about the neglect of this area in development process has further built up their image as that of region's representative.

Electoral Performances of Congress and BJP

Assembly Election in 2009

In 2009 Lok Sabha elections that were held prior to assembly elections in the state, the Congress was the leading party in the Ahirwal region.

In terms of percent vote share, it was first ranking party in six of the total eleven assembly segments. It is interesting to note that of these six assembly segments, five were only from the Gurgaon lok sabha seat from where Rao Inderjit Singh of the Congress was the candidate (Fig.-1). The other lone assembly segment from where the Congress the leading party was the Kosli assembly segment of the Rohtak lok sabha seat. In the remaining four assembly segments which are part of Bhiwani-Mahendragarh lok sabha seat, in three assembly segments (Ateli, Mahendragarh, and Narnaul) the Haryana Janhit Congress Bhajan Lal (HJCBL) was the leading party, whereas, in Nangal Chaudhary, the INLD was the leading party. The BJP remained underperformer in the lok sabha elections. It did not contest the lok sabha seats of Bhiwani and Mahendragarh, and that of Rohtak. It had contested the Gurgaon lok sabha seat and of its six assembly segments falling in the region, it was second ranking party in three assembly segments (Pataudi—SC, Badshahpur, and Gurgaon) and in the remains three segments (Bawal—SC, Rewari, and Sohana) it was third ranking party. In 2009 assembly elections, the Congress had polled 35.08 percent vote in Haryana. Its average vote was 35.41 percent and CV was 33.32 percent. The party won 40 of the total 90 assembly seats, i.e. 44.44 percent. In its comparison, the party had polled 30.12 percent vote in the Ahirwal region. Its average vote in the region was 29.28 percent and CV was 26.50 percent (Table-1). It shows that although the average percent vote for the party was lower in the region but its votes were more uniformly distributed in the region. (Table-1)

The party vote in the region ranged from 17.23 percent in Narnaul assembly constituency to 40.35 percent in Rewari assembly constituency. In total the party had won six assembly seats (Ateli, Mahendragarh, Rewari, Badshahpur, Sohna and Kosli) (Fig. 2a). It shows that the party was able to confirm its dominance of lok sabha elections in the assembly elections in the constituencies of Rewari, Badshahpur and Kosli. It had further improved its performance of lok sabha elections in assembly elections and won the seats of Ateli, Mahendragarh, and Sohana. The party was not out of competition in rest of the five assembly seats of the region where it was defeated. It was runner-up in four constituencies (Nangal Chaudhary, Bawal—SC, Pataudi and Gurgaon) and third ranking party in Narnaul. In terms of percent seats won, the electoral performance of the Congress was better in the Ahirwal region (i.e. 54.54 percent) than the state (44.44 percent). In this election, three seats (Nangal Chaudhary, Bawal—SC, and Pataudi—SC) were won by the INLD, and one seat each by the HJCBL (Narnaul), an independent candidate (Gurgaon).

Source: Election statistics, Haryana

The electoral performance of the BJP In this assembly election was very dismal. It had polled only 9.04 percent vote and won only 4 seats (4.44 percent) in the state. Its average vote was 9.44 percent and CV was 116.52 percent (Table-1). It shows large scale variations in the party's vote across the state. In comparison to the overall picture in the state, the vote share of the party vote in the region was marginally better. It had polled 12.80 percent vote in the region. Its vote share in the region ranged from 2.9 percent in Kosli assembly constituency to 21.53 percent in Ateli assembly constituency. The average vote for the party in the region was 12.50 percent and CV was 73.60 percent. The party, however, failed to win any assembly seat in the region. In terms of percent vote received, it was second ranking party in two assembly constituencies (Ateli, Mahendragarh), third ranking party in three

assembly constituencies (Bawal—SC, Rewari and Gurgaon), fourth ranking party in four assembly constituencies (Narnaul, Pataudi—SC, Badshahpur, and Kosli), fifth ranking party in one constituency (Nangal Chaudhary), and eight ranking party in one constituency (Sohna).

Assembly Election in 2014

Prior to the Lok sabha elections that were held in 2014, a political upheaval took place in the state with its serious implications in the state politics in general and that of Ahirwal in particular. Rao Inderjit Singh, one of the most powerful leaders of the Ahirwal, quit the Congress on September 23, 2013 and joined the BJP. He alleged the Congress for discriminating the region in all spheres of development. Keeping in view his political family background and his long standing in the politics of the region, there were all possibilities that his decision would make serious implications for the Congress. He has remained Member of Parliament from Mahendragarh lok sabha seat (1998, 2004), and Gurgaon lok sabha seat (2009), and Member of Legislative Assembly from Jatusana (now largely part of Kosli) in 1977, 1982, 1991, and 2000. Besides, he has also remained as Cabinet Minister, and Minister of State (various portfolios). In addition to the above, the political legacy of the Rampura House he is carrying clearly indicates that his decision could influence the voters across the length and breadth of the region. The other fact that might have influenced the voters of the region in favour of the BJP was that in 2013 the prime ministerial nominee of the BJP, Narendra Modi chosen the Ahir belt to start his national poll campaign. He addressed a rally of ex-servicemen. The political show and the place were rightly chosen as the region is dominated by villages having large number of persons in defense services. Amit Shah followed Narendra Modi when he held his first rally in Mahendragarh on August 14, 2013. The elections results of the lok sabha elections in different assembly segments of the region showed a complete transformation in the electoral fortunes of different political parties.

The BJP had emerged as the first ranking party in all the eleven assembly segments of the three lok sabha seats. The Congress was either pushed to either second place (Nangal Chaudhary, Rewari, Badhahpur and Kosli), or third place (Ateli, Mahendragarh, Narnaul, Pataudi—SC, and Gurgaon) or fourth place (Bawal—SC, and Sohana). In the 2014 assembly elections, the electoral scene in the region had changed completely for both the Congress and the BJP. In fact, the assembly election results broadly followed the patterns of lok sabha election results. From no seat in the assembly elections from Ahirwal in 2009 assembly election, the BJP won all the eleven assembly seats in 2014 assembly elections. As mentioned above,

the BJP was the first ranking party in all the assembly segments of the region. It clearly indicates that the BJP was able to transfer its electoral success of lok sabha elections completely to assembly elections in the region. In this assembly election, in the Ahirwal region, the percent vote share for the Congress had experienced a negative swing of 18.31 percent in its vote share (from 30.12 percent in 2009 to 11.81 percent in 2014). The BJP, on the other hand, had gained a positive swing of 33.95 percent (from 12.80 percent in 2009 to 46.75 percent in 2014) in the region (Table-1). It was basically as a consequence of this change in the vote percentage received that the Congress failed to win any seat, whereas, the BJP won all the eleven assembly seats. There was negative vote swing for the Congress in all the assembly constituencies of the region. It ranged from 2.55 percent in the case of Mahendragarh assembly constituency to 29.54 percent in the case of Badshahpur assembly constituency. Barring Mahendragarh and Narnaul wherein the party had recorded a negative swing of less than three percent, in all the remaining nine assembly constituencies, the negative vote swing for the party was huge. In this assembly election, the percent vote polled by the party was much higher at the state level (i.e. 20.58 percent) than at the level of region (i.e. Ahirwal) (i.e. 11.81 percent). The CV in the party vote was much higher at the level of region (72.18 percent) than at the state level (57.43 percent). It shows much heterogeneity in the party vote at the level of region. On the other hand, it was the otherwise picture for the BJP. The party's percent vote share at the state level was 33.20 percent, whereas, it was 46.75 percent in the case of Ahirwal. The CV for the party vote was lower at the level of region (20.76 percent) than at the state level (43.13 percent) (Table-1). It indicates much homogeneity in the party vote in Ahirwal region.

Assembly Election in 2019

In the 2019 lok sabha elections that preceded the assembly election, the BJP again emerged as the first ranking party in all the assembly segments of the Ahirwal region. The Congress, on the other hand, had improved its electoral performance than the previous lok sabha elections. It had emerged as the second ranking party in all the assembly segments. Despite emerging as the first ranking party in all the assembly segments of the region, the BJP, however, was not able to transfer its huge electoral success completely in the subsequent assembly election. In 2019 assembly elections, the party won eight of the eleven seats in the region, i.e. Ateli, Narnaul, Nangal Chaudhary, Bawal—SC, Pataudi—SC, Gurgaon, Sohana, and Kosli. The party, however, was not out of battle in the three seats it was defeated (Mahendragarh, Rewari and Badshahpur) and was runner-up in all the three.

Two seats (Mahendragarh and Rewari) were won by the Congress and on one seat (Badshahpur), an independent candidate was elected (Fig. 2c). Whereas, at the state level, the BJP had recorded a positive swing of 3.29 percent (from 33.20 percent in 2014 to 36.49 percent in 2019), there was a negative swing of 5.38 percent (from 46.75 percent in 2014 to 41.37 percent in 2019) for the party in the region in 2019 assembly elections (Table-1). In the case of the Congress, on the other hand, there was a positive swing at both state level and that of the region, i.e. Ahirwal. At the state level, its vote rose from 20.58 percent in 2014 to 28.08 percent in 2019—a positive swing of 7.5 percent) and in the case of Ahirwal, it rose from 11.81 percent in 2014 to 16.41 percent in 2019—a positive swing of 4.6 percent). The CV in the case of the BJP, however, was much lower than the Congress at both state and at the level of region.

Impact of switching over of an important political leader and its impact on the electoral performances of the Congress and the BJP

The impact of switching over of an important political leader, Rao Inderjit Singh, from the Congress to the BJP and its impact on the preferences in favour of or against a political party by majority of the voters of an area/region can be judged on two accounts: one, the electoral performances of the two selected parties in the six assembly segments of Gurgaon Lok Sabha seat (Bawal, Rewari, Pataudi, Badshahpur, Gurgaon and Sohana) from where Rao Inderjit Singh contested the seat on the Congress ticket in 2009 lok sabha election, and on the BJP ticket in 2014 and 2019 lok sabha elections; and two, the Kosli assembly segment, one of the assembly segments of Rohtak Lok Sabha seat, from where Deepender Singh of the Congress was the contestant. In 2009 lok sabha elections, the Congress was the first ranking party in five assembly segments of the Gurgaon Lok Sabha seat when Rao Inderjit Singh had contested the seat from the Congress party, however, when in 2014 and 2019 Lok Sabha elections, Rao Inderjit Singh contested the same seat on the BJP ticket, in all the six assembly segments falling in the region, the BJP became the first ranking party.

The Kosli assembly segment is a part of the Rohtak Lok Sabha seat, however, it is a part of the Ahirwal region and majority of the voters are Ahirs. In the last three Lok Sabha elections, Deepender Singh was the candidate from Rohtak Lok Sabha seat on the Congress ticket. In 2009 Lok Sabha elections, Deepender Singh won the Lok Sabha seat by a huge margin of 4,45,736 votes. He had polled 53.30 percent vote from the Kosli assembly segment. During the subsequent assembly election, the Kosli seat was won by the Congress.

However, things took a dramatic shift during the last two Lok Sabha elections. In the 2014 Lok Sabha elections, although Deepender Singh from the Congress won the seat but the margin of victory was reduced from 4,45,736 votes in 2009 lok sabha election to 1,70,627 votes in 2014 lok sabha election. More importantly, in Kosli segment his percent vote share was reduced from 53.30 percent in 2009 Lok Sabha election to 27.32 percent in 2014 Lok Sabha election. In the assembly election of 2014 that followed the Lok Sabha election, the BJP won all the seats of the Ahirwal region (including that of Kosli) and in terms of percent vote polled, the Congress was shifted to third place with 12.14 percent vote. In 2019 Lok Sabha elections, Deepender Singh of the Congress was defeated by the BJP candidate, Arvind Kumar Sharma by a margin of 7,503 votes. At aggregate level in eight assembly segments, Deepender Singh was leading with a margin of 72,344 votes (excluding postal), however, the difference of 74,980 votes alone in the Kosli assembly segment led to his defeat. The analysis at booth level data for Deepender Singh in Kosli assembly segment alone explains the story. Of the 199 booth in Kosli, in 2009 Lok Sabha elections, there were 89.53 percent booths where the Congress percent share was 40 percent and above. However, the number of such booths was reduced to 18.50 percent in 2014 Lok Sabha elections, and 17.65 percent in 2019 Lok Sabha elections. This is all about the fact that how in adverse conditions only one assembly segment can change the fortunes of a political party in a Lok Sabha seat.

Conclusion

The study concludes with the fact that electoral politics in a federal country like India is constructed at different geographical scales. Even the states constitute different regions, formed with time, on the basis of their unique socio-economic characteristics. This constructs a different kind of electoral politics at the level of region. In the study, this proposition was tested by analyzing the electoral performances of the Congress and the BJP during the last three assembly elections in Haryana (i.e. state level) in general and Ahirwal (i.e. regional level) in particular. The study finds the fact that the Ahirwal region not only retains a different kind of electoral-political character but also plays its own role in the formation of state electoral politics. The study also concludes the fact that the electoral preferences of majority of voters changes if an influential leader of the region changes his alignment from one political party to another. The impact of Rao Inderjit Singh switching over from the Congress to the BJP was certainly one of the crucial factors that had improved the electoral performance of the BJP in Haryana in general and

Ahirwal in particular. It would be an academically enriching exercise if a field-based study is conducted to further analyse the impact of Rao Inderjit Singh's on the voters' choices in the Ahirwal region.

GEOSPATIAL ANALYSIS OF HOUSING AMENITIES IN INDIA

Dr. N. Chendrayudu and Dr. T. Chandrasekarayya

Abstract

A housing unit refers to a physical structure in which people can live (e.g., a house, apartment, condo, mobile home, etc.), whereas a household refers to a group of people who occupy a housing unit as their residence. The National Family Health Survey (NFHS) sample describes key housing characteristics of the household population. Information on household characteristics and housing amenities provides context for understanding socio-economic status of the population. The research paper aims at examine some of the housing characteristics in India and its states based on secondary data collected from NFHS-3 and NFHS -5. The results shows that the housing characteristics such as electricity, improved source of drinking, toilet/latrine facility and using fuel for cooking had significantly augmented in India and its states over a period of 15 years and the housing characteristics are found considerable variations in India and its states.

Introduction

Every family has basic, physiological, and additional needs. Food, clothing and shelter are basic necessities. Of his three basic needs of a human being, protection is one of the basic needs of human existence. It protects us from the vagaries of nature and threats, natural or otherwise. Housing with better characteristics not only provides socio- economic status/condition in society, but also a sense of security and well-being, and high-quality housing provides safeguard. Housing with better amenities are important to mankind because, it provides residents with a safe place and makes it easier to achieve life goals. For centuries, people have been creating homes for themselves, which is a basic need for everyone. Access to basic amenities such as adequate housing, electricity, clean drinking water and sanitation/toilet, and clean cooking fuel is not only an important indicator of a household's socio-economic status, but also an important indicator of the health condition of household members. Improving water supply and sanitation, as well as better management of water resources, can boost economic growth and make a significant contribution to poverty reduction in countries.

Clean water is essential for healthy life among the people. From drinking water to disinfection to modern technology such as gowns, it's so important. Humans and animals require water every day for survival and well-being. Without safe water for just three days, we would all suffer greatly. According to the World Health Organization, more than 2 billion people lack access to safe drinking water and more than 8,00,000 people die from water-related diseases each year (Comer et al, 2018).The National Family Health Survey (NFHS) provides information on a variety of household characteristics that represents living conditions. This research paper describes the housing characteristics of households, including access to electricity, improved source of drinking water, sanitation/toilet /latrine facilities, and fuel used for cooking. Information on household characteristics is based on questions that household survey respondents are required to answer when surveyed by enumerators. Housing provides physical safety and protection from the elements and plays a central role in determining a person's physical and social risk environment (Weir BW et al., 2007). Research results by Soebiyan. V and Bsakina (2021) showed that the main factors influencing household electricity consumption are floor area, number of family members, household income, and number of air conditioners. Access to water is one of the main goals of the United Nations Millennium Development Goals (UN-MDGs) and one of the main goals of the Sustainable Development Goals (SDGs). Fundamentally, everyone needs access to sufficient amounts of clean water for drinking, cooking, personal hygiene and hygiene without putting their health or dignity at risk. Therefore, access to safe and reliable (clean and fresh) water is a fundamental human right (Samra SCJ and Fawzi SCM, 2011). According to the study by Swachh Survekshan Grameen 2022, 95.4 percent of surveyed households have access to a toilet, and 95.4 percent of households with a toilet use it regularly. The 2030 Agenda of Sustainable Development Goals (SDGs) emphasizes the importance of sanitation and sets Goal-6 to "Ensure the availability and sustainable management of water and sanitation for all." Although India's rural households have seen modest improvements in access to toilet facilities in recent decades, they still face high levels of disadvantage, spatial and socio-economic inequality, and exclusion.

Study Region

India is a country that occupies the greater part of south Asia. It is consisting of 28 states and eight union territories, in addition to its national capital is New Delhi, built in the 20th century just south of the historic hub of old Delhi to serve as India's administrative centre. It lies completely in the Northern hemisphere and

Eastern hemisphere between latitudes 84′ N and 37°6'N and longitudes 68°7′ E and 97°25′ E. Prior to independence, Indian mass was under British rule for centuries and neglected the vital housing amenities, which are essentials for survival of humankind. After independence, there is remarkable improvement in basic housing amenities in majority of the states, but in some of the states the condition of housing amenities is still poor. In the present study, all the states were considered in panorama perspective which will be guide administrators to focus on framing the policies decisions on housing amenities. The present study area is Indian union and its 28 states excluding National capital of Delhi. However, the Telangana state value is included in Andhra Pradesh because; the state was not formed at the time of N.F.H.S-3 survey period. Hence, the averages of the amenity value aspects in N.F.H.S-3 and 5 contain combined Andhra Pradesh.

Objectives

The aim of the research paper is to study dynamics of some of the housing characteristics such as electricity, improved source of drinking; toilet/latrine facility and solid fuel used for cooking in India and states between N.F.H.S-3 of 1992-93 and from NFHS-5 of 2019-21.

Database and Methodology

The research paper is based on descriptive research design and data collected from of NHHS-3 (1992-93) and from NFHS-5 of phase-I (2019-20) covers states such as Andhra Pradesh, Assam, Bihar, Goa, Gujarat, Himachal Pradesh, Jammu & Kashmir, Karnataka, Kerala, Maharashtra, Meghalaya, Manipur, Mizoram, Nagaland, Sikkim, Tripura and West Bengal and NFHS-5 of Phase-II (2019-21) for India and 11 States (Arunachal Pradesh, Chhattisgarh, Haryana, Madhya Pradesh, Odisha, Punjab, Rajasthan, Tamil Nadu, Uttar Pradesh, Uttarakhand and NCT Delhi). NFHS-3 collected information from a nationally representative sample of 109,041 households, while, in NFHS-5 phase-I and phase-II, data gathered information from 6,36,699 households. However, the NFHS-5 survey in of phase-II got delayed because of sever COVID-19 pandemic. Arc GIS 10.5 version is applied to trace the dynamics in household amenities in India and its states.

Results and Discussion

The housing characteristics/ amenities in India and its states during the period of NFHS-3 and NFHS-5 have been presented briefly hereunder.

Households with Electricity

Electricity is an essential energy for day today human life. Power shortages not only cause inconvenience to individual consumers due to malfunction of electrical appliances. In the residential sector, it is very important for all consumers to properly manage their daily electricity consumption. Therefore, electricity is an important aspect of modern life and economy. It is used to operate home appliances such as room lighting, fans, electric stoves, air conditioners, computers, electronic devices, and machinery. All these things bring comfort to people. Yunqing Lu et al (2022) focused on studying energy consumption and household characteristics through a dynamic price experiment in communal housing in a smart community in Japan. An interstate comparison of households with electricity amenity is presented (Table-1). In NFHS-3, Delhi being capital city of the nation, the highest per cent (99.3) is noticed, while lowest (27.7) household electricity is observed in Bihar. Based on the highest and lowest house hold electricity amenity the Indian states are grouped into three categories as less than 45 per cent, 45-80 per cent and above 8 per cent More than 90.0 per cent of households have electricity in eight states (Delhi, 99.3, Goa, 96.4; Punjab, 96.3; Jammu & Kashmir, 93.2; Mizoram, 92.3; Haryana, 91.5; Sikkim, 92.1 and Kerala, 91.0) and in the highest category (>80 per cent) there are 16 states showing the high percentage of household amenity. (Table-1 and Fig.-1)

In second category, there are 9 sates distributed in central and northeastern part of the country. There are four states where fewer than half the households have electricity (Uttar Pradesh, 42.8; Jharkhand, 40.2, Assam 38.1 and Bihar, 27.7 per cent) and these states are categorically located in north and northeastern part of the country. The analysis shows that, the physiographic and socio-economic conditions of the states influenced the low rate of electricity amenity. However, in NFHS-5, except Arunachal Pradesh (94.7), Jharkhand (93.8), Assam (92.7), Meghalaya (92.0) and Uttar Pradesh (89.8), all other states possess more than 97.0 percent of the households with electricity amenity and Goa state achieved cent per cent electrification. Country's average household electricity facility also rapidly enhanced from 67.9 to 96.5 per cent which encountered the remarkable improvement in electricity amenity. Thus, rapid improvement in households with electricity found from the period of NFHS -3 of 2005-06 to NFHS -5 of 2019-21, which reflecting within fifteen years.

Households with Improved Source of Drinking Water

Safe drinking water means clean water that does not cause any harm to humans if it comes into contact with it (Fig. 1 and Table-1 and 2).

Source: National Family Health Survey-3 and 5.
Note: Improved sourse drinking water for households.

To be safe, water must have sufficiently low concentrations of harmful contaminants. Safe and readily available water is important for public health, whether used for drinking, domestic use, food production, or recreational purposes. In India, widespread access to safely managed drinking water could prevent nearly 14 million Disability-Adjusted Life Years (DALYs) from diarrheal diseases, resulting in an estimated cost of up to $101 billion. It is estimated that this will lead to a reduction in drinking water, which is one of the most important and basic needs of humans. It is the most basic and important element necessary for humans to survive. Access to safe and clean drinking water is critical to maintaining health and well-being. Drinking water has many important functions in the body, including regulating body temperature, maintaining healthy skin, and promoting digestion (Amend, Sarah R et al., 2016). As per NFHS improved safe drinking water means "tap water in the apartment/garden/property, pipes to neighbors, public taps/standpipes, tube wells or boreholes, protected boreholes, protected springs, rainwater, tanker trucks, small tanker trucks, bottled water, and local communities, reverse osmosis (RO) system ". An interstate comparison of households with improved source drinking water is presented (Table-2 and Fig.-1).

The household access found to improved highest source of drinking water (piped water or water from hand pump) is found highest in Bihar (96.1) state and lowest percentage of drinking water amenity is observed in Manipur (52.1). By considering the highest and lowest household drinking amenity the Indian states have been grouped into three categories as less than 65, 65-80 and above 80 per cent and the same range group is adopted for NFHS-5 also. In this amenity, three states (Bihar 96.1, Haryana, 95.6 and Punjab, 99.5) exceed 95 per cent. In lower category, there are four states (Manipur, 52.1; Jharkhand, 57.0; Meghalaya, 63.1; and Nagaland, 62.8) in low category in which more than one-third of households obtain water from an unimproved sources like cannels, rivers, streams, ponds, lakes tanks and open dug wells. In seven states such as the available amenity is moderate ranging from 65-80 percent and remaining percent of households obtain their drinking water from unsafe sources, which in many cases declaim the health conditions. Majority of Indian states possess with high percent of improved source of drinking facility around 18 states come under this category. While in NFHS-5, majority of states have access to improved source of drinking water (Table-3). Therefore, substantial raise in the household access to improved source of drinking from NFHS-3 of 2005-06 to NFHS-5. Thus, in NFHS-5 the least percent improved source of drinking water facility is found in Manipur (77.0) and highest per cent (99.50) is noticed in NCT of Delhi state.

Table-3: Households having Toilet/Latrine Facility

Sr. No	India/State	NFHS-3	NFHS-5

(28)	Kerala	96.1	99.7
(29)	Tamil Nadu	42.9	77.5
	India	44.6	80.6

Source: National Family Health Survey-3 and 5.
Note: Figures are given in percent.

It is interesting to present that possess above 90 per cent and about achieved more than 95 per cent in possessing improved source of safe drinking water. Geographically, all the sates achieved tremendous achievement except a few states which located in hilly terrain.

Households with Toilet/Latrine Facility

Sustainable Development Goal (SDG) 6.2 calls for universal access to safely managed sanitation by 2030. Ensuring universal access to safe sanitation by 2030 is a development priority for India. It helps to achieve better physical and mental health results. While, the proportion of people in India with access to safe sanitation has been increased dramatically over the past three decades. However, in some of the Indian states are at the highest risk of not having access to safe sanitation during this period. The most disadvantaged and excluded are households from backward areas belonging to weaker sections of society, such as Poor wage earners, Scheduled Tribes and Scheduled Castes. Therefore, in addition to accelerating rural sanitation development efforts to achieve the SDGs, there is an urgent need for complementary measures that focus on the socio-spatial conditions of backward areas, vulnerable groups, and households in rural India. According to Jain, A et al. (2023), the prevalence of zero hygiene (defined as people defecating in the open due to lack of access to a household toilet) across India has increased. During NFHS-5, considered uses an improved sanitation facility (toilet facility) as "flush to piped sewer system, flush to septic tank, flush to pit latrine, flush to don't know where, ventilated improved pit (VIP)/biogas latrine, pit latrine with slab, twin pit/composting toilet, which is not shared with any other household". State wise comparison of households with any toilet/latrine facility is presented (Table-3 and Fig. 2).

Table-3 reveals that, the substantial variations across states in access to any toilet/latrine facility. As per NFHS-3, the proportion of households with access to any toilet/latrine facility ranges from 25.0 per cent or less in four states (Bihar, 25.2; Jharkhand, 22.6; Odisha, 19.3 and Chhattisgarh, 18.7) to over 95.0 per cent in Manipur, Kerala, Tripura and Mizoram. Based on these observations, the Indian states have been grouped as less than 45, 45-70 and more than 70% classes. The analysis designates that, majority households with low toilet facility are found in central part of the country and interestingly high facility is noticed in north eastern states except Rajasthan. However, the Swachh Bharat Mission, Swachh Bharat Abhiyan, or Clean India Mission is a country-wide campaign initiated by the Government of India on 2nd October 2014 to eliminate open defecation and improve solid waste management and to create Open Defecation Free (ODF) country.

Fig. 2

As a result, the improved sanitation/toilet/latrine facility India and its states significantly improved. The NFHS-5 reveals that in sixteen states (NCT of Delhi, Haryana, Himachal Pradesh, Jammu & Kashmir, Punjab, Uttarakhand, Chhattisgarh, Arunachal Pradesh, Meghalaya, Mizoram, Nagaland, Sikkim, Goa, Andhra Pradesh, Karnataka and Kerala) over 70.0 percent (high) of households have access to improved sanitation facility and no state falls under low percent group and only three states namely Bihar, Jharkhand and Odisha have come in moderate group. Even though, 22 states possessed above national (80.6) average percentage, there is dire need to a take steps to achieve open defecation free country by 2030.

Households Using Solid Fuel for Cooking

A fuel is a type of substance that burns to produce heat or electricity. It can be in solid, liquid, gaseous or natural form. Reliance on cheap and dirty solid fuels such as firewood and other dry biomass, cow dung and coal for cooking exposes millions of Indians to dangerous air pollution, leading to significant health risks. Clean cooking fuels provide access to energy for the country's poor. This will minimize health problems and premature deaths especially among women and children, and help India reach its net-zero targets by reducing carbon emissions. As far as India's energy scenario is concerned, the most commonly used fuels in India are LPG, PNG, coal, kerosene, dung meal, firewood, crop residue, and to some extent electricity. As per NFHS, solid fuels used for cooking considered such as “coal/lignite, charcoal, wood, straw/shrub/grass/crop waste, and dung cakes”. Balakrishnan et al. (2019) found that of the 1.24 million deaths caused by air pollution in India in 2017, 6,70,000 were due to ambient particulate pollution and with an additional of 4,80,000. This is due to household air pollution as point out by people. Although the main sources of particulate pollution in the environment are external, domestic air pollution is primarily caused by the combustion of solid fuels for cooking and heating. An interstate comparison of households with using solid fuel for cooking is presented in Table-4 and Fig 2.

The smoke from solid fuels poses a health hazard when inhaled. As per NFHS-3, the proportion of households relying on solid fuels for cooking range from a lowest in Delhi (9.3 per cent) to a highest in Bihar (89.7 per cent) and over 85.0 per cent observed in four states: Chhattisgarh, Orissa, Jharkhand, and Bihar. Other states with particularly low use of solid fuels are: Mizoram and Goa, where around one-third of households rely on solid fuels for cooking. In fact, with the exception of Delhi, in all other states, significant per cent of households relies on solid fuels for cooking.

Table-4: Households having Using Solid Cooking Fuel

Sr. No	India/State	NFHS-3	NFHS-5
(1)	NCT of Delhi	9.3	0.8
(2)	Haryana	69.1	40.1
(3)	Himachal Pradesh	68.9	47.7
(4)	Jammu & Kashmir	59.5	30.2
(5)	Punjab	54.9	22.1
(6)	Rajasthan	77.2	58.5
(7)	Uttarakhand	61.7	40.5
(8)	Chhattisgarh	86.7	66.4
(9)	Madhya Pradesh	80.3	59.3
(10)	Uttar Pradesh	81.7	50.3
(11)	Bihar	89.7	62.0
(12)	Jharkhand	89.1	67.8
(13)	Odisha	88.6	64.9
(14)	West Bengal	79.2	59.1
(15)	Arunachal Pradesh	67.7	46.6
(16)	Assam	75.8	56.4
(17)	Manipur	64.7	29.6
(18)	Meghalaya	72.2	63.4
(19)	Mizoram	34.1	16.0
(20)	Nagaland	76.0	56.5
(21)	Sikkim	52.4	20.7
(22)	Tripura	80.4	53.0
(23)	Goa	33.3	2.8
(24)	Gujarat	52.3	32.2
(25)	Maharashtra	48.1	18.2
(26)	Andhra Pradesh	66.3	15.6
(27)	Karnataka	63.8	19.4
(28)	Kerala	71.4	27.4
(29)	Tamil Nadu	60.5	15.4
	India	70.8	40.6

Source: National Family Health Survey-3 and 5.
Note: Figures are given in percent.

By considering the lowest and highest solid fuel consumption the states were grouped as less than 35, 35-65 and more than 65 per cent. In low category, only two states namely NCT of Delhi, Mizoram and Goa represented less than 35 per cent, which shows, high dependency on other than solid fuels for cooking (i.e. clean fuel such as Electricity, LPG/natural gas, biogas). However, in NFHS-5, nearly all of the households in NCT of Delhi (99.2 percent) and Goa (97.2 percent) are relying on clean fuels for cooking. In seven states (Punjab, Mizoram, Sikkim, Maharashtra, Andhra Pradesh, Karnataka and Tamil Nadu) over 75.0 per cent of households using clean fuel for cooking. Only in the states of Chhattisgarh and Jharkhand, more than 65 per cent (high category) households using solid fuel and in rest of the states, households are using clean fuel. Thus, findings reveal that substantial change has been noticed in the use of solid fuel (coal/lignite, charcoal, wood, straw/shrub/grass/ crop waste, and dung cakes) to clean fuel (electricity, LPG/natural gas, and biogas) indicates country's advancement in cooking fuel and in a line to conserve natural vegetation and minimize the air pollution which has been leading to overcome from health hazardous conditions to safe health positions.

Conclusion

Based on the findings, it can be concluded that, a substantial variation exists across states in the basic housing characteristics such as electricity, improved source of water, toilet facility and using solid fuel for cooking. However, a significant increase in housing characteristics such as households with electricity, an improved source of drinking water, sanitation/toilet facility and clean fuel for cooking has been noticed from NFHS-3 of 2005-06 and NFHS-5 of 2019-21 in India and its states, which resembles the government initiations and societal transformation from traditional to modern and health hazardous to safe and leading comfortable life.

ASSESSMENT OF LANDUSE AND LANDCOVER CHANGES USING GIS ANALYTICS OF RIVER KALJANI BASIN IN DOOARS, NORTH BENGAL

Mantu Das and Dr. Snehasish Saha

Abstract

The need of studying Land use and the existing Land Cover situation has got tremendous impetus after Second World War conditions and was highly geared during the 1960s though a handful of methodological approaches started flourishing from 1980s. With the advent of satellite imageries and legacies of air photographs resulted in precise computation of land use patterns. The novelty of such studies lies in the fact of assessment of human civilization and development. The present work has been framed taking the Kaljani river basin in the Sub-Himalayan North Bengal plains of Duars of West Bengal (India) and to compute the changes in view of environmental loss and alterations of land using GIS techniques for a 20 years temporal frame and satellite imageries especially to document the facts. The authors have used Landsat 8 OLI/TIRS, Landsat 5 TM, and also Landsat 5 TM for situations of 2019, 2010 and 2000 periods respectively. Supervised classification has been used as a user guided approach involving selection of training sites as reference for the class categorization associated with pixel selection. Authors followed four types of accuracy evaluations for land use class derivations like User accuracy, Producer accuracy, Overall accuracy and Kappa coefficient (K) and thereby to frame the Error matrix calculations to assess the overall condition and in all cases the Kappa coefficient qualified the degree of accuracy becoming more than 80% for all the three time series data. As a major finding seven types of land use classes were derived and the authors have tried to find out the socio-environmental implications. The study may be fruitful to document the land use variations within the basin and identify the land cover alterations.

Introduction

Land is a valuable natural resource on which human activities have taken place and is highly influenced by the management practices. Although the words "landuse change" and "landcover change" are sometimes employed interchangeably, they

have distinct meanings. The 'human activity or economic function connected with a site specific section of earth's surface' is referred to as land use (Lillesand et al., 2013; Das et al., 2019), they are typically not visible immediately on satellite photos' (Bhatta, 2011), while land cover alludes to "the vegetation, water bodies, and man-made structures that cover the earth's surface" (Alam et al., 2019; Burley, 1961). Multiple changes in land use are the result of rising human population and the associated demand for more resources, the most important of which are minerals, soil, and water. The long-term sustainability issue is more significant than climate change, yet it is amplified by it (Das et al., 2019). The rate (temporal) and geographical scale modifications of land surface, mostly in the form of LULC change, are unprecedented and, influence some components of earth systems like-biodiversity, physical components of biosphere, lithospheric characteristics etc. Two basic features of land transformation are Land Use Alteration (LUA) and Land Use Intensification (LUI) (Das et al., 2019). LULC change has a great impact on even biogeochemical cycle. Humans' ability to influence the rate and pattern of LULC change is largely determined by their social, economic, and political traits (Ojima et al., 2019). Land Use Land Cover Change (LULCC) is an important component of global environmental change studies now (Jensen, 2009).

Landuse and landcover is a local and site-specific system that focuses on global environmental issues as a whole. These changes have negative implications on loss of biodiversity (at three levels: genetic, species, and ecosystem), desertification, climate change, and changes in human behaviour, among others. LULC change studies attempt to interpret (i) where change is occurring, (ii) what types of land cover are changing, (iii) the types of transformation occurring, (iv) the rates or amounts of land change, (v) the driving forces and proximate causes of change, (vi) the adverse effects on lithosphere, biosphere and atmosphere if over use of land is questioned commissioning excessive cropping practices and (vii) what are the sustainable management practices with spatio-temporal changes on the earth surface (Lillesand et al., 2015; Loveland et al., 2000; Reddy, 2008). The future change patterns or trends of the LULC, which are generally generated by simulation modelling, are also an important aspect of such analyses. Models frequently include empirically fitting the evaluation system to a historical pattern of change, then extending that pattern analysis for future projections to determine when, where, and why LULC changes occur (Brown et al., 2000). That’s why more reliable/accurate LULC data for time points will be a very crucial need for imposing any local or regional and consistent policy in respect to sustainability and to initiate accurate monitoring of LULC change (Belward et al., 1999).

There are many scientific ways to monitor or detect LULC changes on the earth surface over time (Bhatta, 2011; Campbell & Wynne, 2011; Jensen, 2009; Li et al., 2014; Lillesand et al., 2013; Nelson, 1983). In the past, academies mapped LULCC over smaller areas using field data and aerial images but less suitable for larger areas. As satellite images have high temporal coverage, remote sensing (RS) has become a more dependable one for spectrally sensitive changes of the planet since the last decade of the twentieth century especially inevitable for inaccessible places. The information executed through the digital technology (Space based technology) is also crucial for model building and other natural and cultural processes (Jensen, 2009). Such Remote sensing data with varying resolutions and descriptive models, provide a unique opportunity to record past and present LULC patterns for detail study (Bhatta, 2011; Lillesand et al., 2013; Lillesand et al., 2015; Reddy, 2008). Over the years, LULC switch assessment has been accomplished efficiently and cost-effectively using satellite data (Landsat OLI/ETM+/TM/MSS). Assessing LULC changes has been the most widely used and well adopted application of satellite data from an operational standpoint (Nelson, 1983; Singh, 1989; Turner & Meyer, 1994). The present study is taken up to delineate LULC zones over a volatile riverine trajectory.

Study Region

The research area is mainly situated in the newly formed Alipurduar district (25th June, 2014). This is the northeast corner of the state bordering Assam on the East, Bhutan on the North and Bangladesh on the south of West Bengal and comprises some part of Jalpaiguri district (West Bengal) and a little bit of portions of Southern Bhutan which covers an area of 1,190 km2. Kaljani basin is the sub-basin of Torsa drainage system (sub-basin of Brahmaputra drainage system). Areal extension of Kaljani basin is 26o16/30// N to 26o55/20// N and 89o21/17// E to 89o37/10// E. Kaljani basin is the part of Darjeeling Sub-Himalaya and comes under piedmont tract of North Bengal Dooars. Upper catchment of this basin comes under hilly areas (highest elevation approximately 2,200 m above M.S.L.) and lower catchment comes under plain areas known as Tarai-Dooars region (lowest elevation approximately 50 m above M.S.L.). The total basin area sub-divided into three geomorphic units i.e. upper hilly or mountain area; middle piedmont area and lower plain area. In every part of the basin distinct hydro-geomorphologic characteristics are visible.

Objectives

This research work aims to examine the land use and land cover changes in the Kaljani River Basin (KRB) between the time periods from 2000–2010–2019 and its impact on the river.

Database and Methodology

In this study three satellite images have been taken from 2000 to 2019 with a 10 years interval. It is required to have at least two time periods of data to compare in order to monitor LULC change. For assessing LULC changes in any area, a remote sensing technique generally requires the use of satellite images from two or more dates. The imageries used in this investigation were chosen based on their spatial resolution compatibility (30 x 30 m). The LANDSAT data archive, which contains pictures that are sufficiently consistent with data from previous missions, enables for long-term regional and global LULC change analysis (Irons et al., 2012). For LULC change analysis in the Kaljani basin, we employ cloud free scenes from LANDSAT-TM (2000 and 2010) and LANDSAT-OLI (2019). Because the imagery had previously been pre-processed, no radiometric calibrations or atmospheric adjustments were needed. (Table-1)

Table-1: Characteristics of Satellite Imageries

Sl. No.	Satellite Data	Path	Raw	Date of acquisition	Spatial resolution
1	Landsat 8 OLI/TIRS	138	41,42	November 14, 2019	30 x 30
2	Landsat 5 TM	138	41,42	October 12, 2010	30 x 30
3	Landsat 5 TM	138	41,42	November 17, 2000	30 x 30

Error Correction before Utilizing Raster Data

Multi-spectral satellite imagery (raster data) having various kinds of error like cloud cover, sun inclination, poor reflectance etc. Therefore, error correction (radiometric and atmospheric correction) is very essential before utilizing the data. In this context, the researchers have been proceed system provided atmospheric correction, raster image enhancement (linear), high pass filtering with edge sharpening (filter level size: X=3 and Y=3) for better identifying the pixel character.

Results and Discussion

LULC Classification

Through the digital process of feature recognition and classification, the changing nature of LULC was acquired from multiband raster imageries. Spectral information such as colour band is one of the main types of information used for the purpose of image classification as well as interpretation. In this context, image conversion from FCC (False colour composite) to TCC (True colour composite also called natural colour composite) map has been developed through the systematic image classification technique. Image classification is designed for an automatic categorization of pixels with a common reflectance range into a specific LULC class (Lillesand et al., 2015). It is noticed that image classification method has been used as a tool in mapping from remotely sensed data. Supervised classification is a user-guided classification technique that involves selecting training sites as category references (Lillesand et al., 2015). Many approaches, such as parallelepiped classification, K-nearest neighbour, minimal distance to mean classification, Gaussian maximum likelihood, linear discriminant, features space, and others, are used to accomplish supervised image classification (Lillesand et al., 2015; Reddy, 2008; Bhatta, 2011). Using ArcMap (10.5) software, we employed a frequently used maximum likelihood classifier (Foody et al., 1932) for LULC classification in this work. The maximum likelihood/Bayesian classifier method examines both the variance and covariance of spectral response patterns quantitatively, and each pixel is allocated to the class with the highest likelihood of connection (Alam et al., 2019; Shalaby & Tateishi, 2007). A total of 7 LULC classes i.e. water body, sand deposit, dense forest, open forest, agricultural land, bare soil and settlement area were determined. Post-classification of the LULC raster layer was cross verified with the help of Google Earth pro software in a systematic statistical way. (Table-2)

Accuracy Checking

Any map is nothing more than a model or a generalization, so it has some oversight (Dicks & Lo, 1990; Maling, 2016; Smits et al., 1999) because primarily derived LULC map from satellite data is not standard one due to error in remote sensing data (Hord & Brooner, 1976; Congalton, 1991). Because LULC classification is prone to mistakes, the output (maps) must be submitted to the test for correctness using a trustworthy statistical approach (Foody, 2002).

Table-2: Description of LULC Categories

Class	Description
Agricultural land	This class represents the cultivated land (Rabi and kharif crops).
Settlement area	The residential areas are represented under this class, road, bridge, industrial area and other paved surface.
Dense forest	This classification refers to the coniferous forest that covers the surrounding mountains.
Open forest	This class includes tea plantation (Tea garden), small deciduous forest and sparse vegetation etc.
Sand deposit	This class represents the dry river channel with full of sand, gravel and boulders etc.
Bare soil	This class represents the bare land and other soil surface that are bare of greenery throughout the entire year, bank soil, landslide area etc.
Water body	This class represents the open water bodies such as river, ponds, cutoffs, pools etc.

Source: Prepared by Authors

As a result, LULC maps frequently come with an accuracy assessment index that includes a detailed description of the sampling design (including sample size and, if applicable, stratification details), an error matrix, the area or proportion of area of each category according to the map, and descriptive accuracy measures like user, producer, and overall accuracy (Congalton, 1991; Lillesand et al., 2015; Olofsson et al., 2013; Trodd, 1995). Cohen's kappa (k) is a frequently used statistical measure for determining inter-rater concurrence between categorical variables that was introduced by Cohen in 1960 (Alam et al., 2019). The accuracy of all raster layers (2000, 2010, and 2019) was evaluated in this study by the production of an error-matrix (Stehman, 1997; Lard, 1995; Foody, 2002; Congalton, 1994). The sample design used in accuracy testing has an impact on the accuracy assessment's dependability (Muller et al., 1998; Stehman, 2001). In order to test accuracy, a stratified random sample design was used (Stehman & Czaplewski, 1998). Geo-statistics has been used to design an efficient sample (Atkinson et al., 2000). For this purpose, 50 samples for each LULC category have been selected.

Sample points have been selected with proper care and significant ways to provide a representative and meaningful basis (Hay, 1979). So, ground truth validation is the main standpoint (Campbell & Wynne, 2011). The generated maps of the time periods - 2000, 2010 and 2019 revealed an overall accuracy of 85.14%, 89.14%, 89.14% and kappa coefficient of 0.8267, 0.8733 and 0.8732 respectively. The precision of all three raster layers is satisfactory in general. The overall accuracy of LULC maps is estimated to be between 85 and 90% (Anderson, 1976; Shalaby & Tateishi, 2007). In case of Kappa coefficient, results are also reliable and standard one (Lillesand et al., 2015). As a result, the acquired results can be regarded as more dependable to a greater extent. The Eq. was used to calculate the overall accuracy and kappa coefficient (4) (for details see Table-6).

UA (%) = No. of correctly classified pixels in each category/Total no. of classified Pixels in that category (Row total) × 100 (Eq. 1)

PA (%) = No. of correctly classified pixels in each category/Total no. of Reference pixels in that category (Column total) × 100 (Eq. 2)

$$OA = \frac{\sum_{=1} xii}{x} \text{(Eq. 3)}$$

Note: Where xii is the diagonal elements in the error matrix, x is the total number of samples in error matrix.

$$\text{Kappa coefficient } (\text{K}) = \frac{n\sum_{i=1}^{r} xii - \sum_{i=1}^{r} xi + x + i}{n^2 - \sum_{i=1}^{r} xi + x + i} \text{(Eq. 4)}$$

Note: where r is the number of rows in the matrix, r_ii is the number of observations in row i and columni, xi+ x_(i+) and x_(+i) are marginal totals for row i and column i respectively and n is the total number of observations. (Table-3, 4, 5 and 6 and Fig. 1)

In remote sensing, primarily obtained multi-spectral raster data is associated with several errors (Both radiometric as well as atmospheric error) (Lillesand et al., 2013; Bhatta, 2011) (Fig. 1). The egregious disadvantages of remote sensing include the incapability of many sensors to acquire data and information over the earth surface due to cloud cover, inclined sun angle, distinct phenomena can be pixelated (Bhatta, 2011) if they appear the same to the sensors, and satellite imagery resolution may be too coarse for detailed mapping and exclusive tiny contrasting areas; on the other hand, high-resolution satellite imagery is more cost effective. Despite these disadvantages, remotely sensed satellite data (LANDSAT OLI/ETM+/TM/MSS) have been used to identify changes on the earth surface over time in a variety of land use (crop land, building construction, paved surface etc.) and land cover (Forest, water body etc.) attributes (Bhatta, 2011; Lillesand et al., 2015; Reddy, 2008). This is especially true in distant areas, which are frequently inaccessible and hence difficult to obtain data from using standard approaches.

In this situation, researchers/learners/planners frequently employ remotely sensed data in a scientifically sound manner to give data on resource inventory and land use, as well as to discover, monitor, and quantify evolving landscape patterns.

Landuse Change Analysis

Over the last three decades, the Kaljani basin has seen significant changes in LULC over its length and width. Figure 2 shows the changes in LULC within the research region across the specified time periods (2000–2010–2019). (Fig. 2)

Dense Forest

The research area's dense forest is the biggest of all the recognized classifications. Dense forest is very common in hilly/mountain areas. Upper catchment of Kaljani basin is mainly covered up with dense forest (like Buxa forest, Buxa hill forest, Gabour Bachhara forest, Dakshin Barajhar forest). The result shows that this LULC category shared 35.38% area of the basin in 2000 and decreased in 2019 (33.69%) but an exceptional case happened in 2010 (2.58%), resulting in a positive change. The present trend is normal due to population pressure, may be illegal logging and lack of sustainable management techniques in forest areas are the two reasons. Local people experienced such kind of LULC changes in their daily life. To be specific Forest is the house of primitive tribal people and must be saved. But over time they are losing their traditional forest based lifestyle due to destruction of forest land and it is very common in Buxa and surrounding forest areas. Figure 3 clearly stated that 144.93 sq.km areas have vanished in between 2010 to 2019 and also showed 38.35 sq.km area totally disappeared during the selected time periods (2000-2019).

Agricultural Land

The agricultural land revealed a continuously declining trend in the Kaljani basin area. The total area under this category has been 24.88 %, 23.71% and 16.60% of the total area in 2000, 2010 and 2019 respectively. There has been a decreasing trend of 13.81 sq.km area from 2000 to 2010, 93.47 sq.km from 2010 to 2019 and a collective reduction of 107.28 sq.km from 2000 to 2019 in agricultural land. It is noticeable that, considerable portion of agricultural land was lost and reduced due to rapid population growth with increasing demand for settlement areas and urbanization.

Fig. 2

Sand Deposit

Piedmont areas, even foothill plains have witnessed huge concentration of sand, boulders, cobbles, pebbles etc. throughout the year. In the studied basin, the upper part of Kaljani drainage network has been filled up with different sizes of particles and gradually increasing its bed elevation. The result shows 0.99% of total basin area covered with sand deposits and has been increased in 2010 (4.37%) and 2019 (4.19%). There has been increased of 40.18 sq.km from 2000 to 2010, little bit reduced from 2010 to 2019 (4.47 sq.km) but has witnessed net increase of 55.71 sq.km from 2000 to 2019. Unplanned circumstances (like population pressure and building construction in mountain regions, rudimentary practices of cultivation along the mountain slopes etc. are the main reasons for the supply of load and high concentration of sand and other types of particles in river bed. And various natural events e.g. torrential rainfall, earthquakes though very less, landslides etc. are also responsible for such a changing scenario. Excessive bed deposition and avulsions are the ecological problems of Kaljani River. It is noticeable that all the major rivers of North Bengal like Teesta, Torsa, Kaljani, Raidak, Lish and Ghish are suffering from unnatural siltation. Deforestation, civil construction, and several other increased human activities in hills are causing loosening of the top soil and increasing discharge of debris. Therefore, residential areas alongside the Kaljani River have witnessed worse flood events almost every year due to low carrying capacity of monsoon runoff.

Bare Soil

This class of LULC represents open uncovered fallow land. It may be unfertile agricultural land; wipe away lands by landslide or unplanned cutting process, bank soil etc. In the study area lands under this category have been found with 4.20%, 3.27% and 6.34% in 2000, 2010 and 2019 respectively. Statistics show that the amount of bare soil gradually increased in Kaljani basin over time, it's about 33.00 sq. km from 2010 to 2019 and 21.94 sq. km from 2000 to 2019. Deforestation in the Piedmont area, as well as an expansion in industry and building sites such as brick kilns and highways, have all contributed to the growth of this class.

Open Forest

Open forest especially in the form of plantation (Tea garden), social forestry and scattered vegetation is a LULC class of such a category that has reduced slowly. It is mapped through satellite data of 24.84%, 17.93% and 19.09% in 2000, 2010 and 2019 respectively under this category in Kaljani basin.

Open forest area has decreased about 82.17 sq.km in between 2000-2010 and increased by 3.57 sq.km from 2000 to 2019, encroaching the agricultural land, bare soil areas side by side, little bit of portion added from dense forest.

Waterbody and Settlement

Water body represents the open water surface (Table-2) area on the earth surface. This LULC category revealed a positive growth in the basin area. In 2000 total covered area of the water body was 13.12 sq. km (1.14%) and over time gradually increased about 1.14% and 2.45% in 2010 and 2019 respectively. In the Kaljani basin, LULC fluctuations are more obvious; one of them is the expansion of the settlement area. The majority of the structures are residential, although there are a few commercial ones as well, the total area under settlement has been 8.61%, 13.98% and 17.65% in 2000, 2010 and 2019 respectively, registering a total growth of 63.85 sq.km from 2000 to 2010, 34.12 sq.km from 2010 to 2019 and total net growth of 97.97 sq.km in the selected time period (2000 to 2019). The settlement areal expansion has been mostly encroaching the agricultural land, bare land, open forest areas etc. particularly expanding along the road and around the core area (e.g. Hamiltonganj and Alipurduar in Alipurduar district); the increasing settlement area adversely affects the environment quality, loss of biodiversity etc.

Conclusion

The study reveals some exodus results especially reduction of all three types of forest cover and which is indicative of probable misuse and natural loss of forest resources during the last 20 years period. More overwhelming scenario is probating the fact that agricultural lands have declined to a remarkable percentage and which is actually attributing to the volatile nature of seasonal submergences and pocket floods within the basin and that might be due to avulsion and an branching of the channels. Furthermore, huge bed filling scenarios and negligible bed slope characteristics have been attributed to the spate of the channel and occasional deluges. As a fact of provenance, the sand deposits and their percentage share is contravening influence of bank side submergences and diluvia of land under marginal cropping usage. Contextually development of settlement areas is also increasing keeping an incremental trend and dependency on land cum man-land share is turning into challenges over time especially agricultural production point of view. Increasing trends of water bodies are almost pointing out reappearances of channel off shoots and paleo channel features but excessive replenishments are reasonably resulting in their disfigurations for every next year from the year of appearance.

Multi thread channel patterns with anastomosing character or pattern is viewable in Kaljani basin and seriously approves the factuality of occasional flood scenarios.

GROWTH PROFILE AND SIGNIFICANCE OF HERITAGE-RELIGIOUS TOURISM IN EASTERN REGION, UTTAR PRADESH

Kunal Jha and Kapil Kumar Gavsker

Abstract

Growth and development of tourism primarily hinges on cultural factors including heritage and religious sites. Modern tourism is driven by and at the same time contributes towards the conservation and preservation of heritage-religious centers of tourism attraction. Drivers which affect influx of tourists at heritage sites include its cultural, religious, monumental significance and infrastructural improvements. There are many historical and heritage sites in state of Uttar Pradesh which attract a significant and few of them a majority of tourists including both domestic and foreign tourists. There are marked geographical variations in the tourists flow across the districts of the state. However, with a changing policy planning, a few of them are going through revitalization and redevelopment stages to further promote culture and tourism consequently contributing to economy of Eastern region. Based on secondary data, the present research paper focuses on to study trends, growth and spatial-temporal pattern of tourism in Uttar Pradesh especially in its Eastern region. Present study unravels and highlights the emerging challenges in tourism sector and why they need to be tackled for a sustainable tourism strategy in the state.

Introduction

Tourism has emerged as one of the most promising economic activities in modern times. It is now being actively integrated with economic development planning in most of developing countries (Rasool et al., 2021). A policy shift can be sensed in terms of developing all such potential places which can attract more tourists and consequently contribute to overall economy. The United Nations World Tourist Organisation (UNWTO) stated that "Tourism comprises the activities of persons travelling to and staying in places outside their usual environment for not more than one consecutive year for leisure, business and other purposes". In 2019, the global tourism peaked to 1464 million (UNWTO).

Tourism is well established part of heritage (Light, 2015) and it is interconnected since heritage is blend of cultural, social, historical and architectural image of a society. Heritage, being both tangible and intangible, has always been the point of attraction for tourists around the globe and "heritage tourism is a major economic activity in almost all countries of the world" (Light, Ibid). Thus, heritage places include ancient monuments, religious and spiritual sites, and places of cultural amalgamation which always remained preferred sites for tourists. Hall and McArthur (1998) illustrated that "[H]heritage is a part of a region's resource base, but only exists as such when it has been determined to have some utility function" (cited by Boyd 2002:212). The Organisation for Economic Co-operation and Development (OECD, 2009) highlighted that "[C]cultural tourism is one of the largest and fastest-growing global tourism markets. Culture and creative industries are increasingly being used to promote destinations and enhance their competitiveness and attractiveness." In a developing country like India, the rich and diverse cultural heritage and resources can act as the axle of tourism development. In India, cultural tourism is a sector that focuses on those geographical areas which reflect the art, architecture, religion and associated elements. Menon et al. stated that "cultural tourism is one of the biggest attractions for the tourist and it is a known fact that many travellers who plan to visit India focus their trip on cultural tourism" (2021). The fact is that the tourism industry thrives on the needs, tastes and perceptions of visitors.

Study Region

The study primarily focuses on the tourism development in Uttar Pradesh with special emphasis on its eastern region. The study also analyses the domestic and foreign tourism in India and the Empowered Action Group (EAG) States which include Bihar, Chhattisgarh, Jharkhand, Madhya Pradesh, Orissa, Rajasthan, Uttaranchal, and Uttar Pradesh. Uttar Pradesh is one of the largest states in India which has a diverse cultural heritage. Uttar Pradesh comprises seventy-five districts with a population of 199.58 million as per the Census of India 2011. It's a fact that a few states in a country play an important role in attracting tourists for various purposes. Uttar Pradesh is one such state in the country which draws a huge number of tourists not form domestically but globally as well. The state has seen some sort of transition in tourism profile as tourists now turn to several places of religious and cultural importance rather than visiting recreational sites only. Thus, the share of religious places in attracting tourists has increased over the past few years in the state. In terms of tourist footfalls, the state is consistently ranked among the top five states in the country. Uttar Pradesh has emerged as the top destination for

attracting the highest number of domestic tourists in the year 2019. State's tourism significantly contributes to the state's economic growth and employment generation both direct and indirect, making it an important focus area for the government.

Objectives

The focus of the paper is to study the growth and development of tourism in eastern region of Uttar Pradesh (a) to analyse trends and growth of tourism in India and EAG states; (b) to study spatial concentration of tourism growth in districts of Uttar Pradesh; (c) to examine the growth pattern of tourism in Eastern Uttar Pradesh; (d) to critically discuss recent developments in tourism development policy and planning in Uttar Pradesh and their implications for sustainable tourism.

Database and Methodology

The present research adopts a descriptive and analytical framework. The entire study is based on secondary data collected from various sources such as published books, journals, reports, documents and websites. The secondary data is taken from Indian Tourists Statistics at a Glance-2020, Ministry of Tourism, Government of India; Annual Report 2019-2020/Annual Report 2020-2021, Ministry of Tourism, Government of India; Uttar Pradesh Tourism Statistics, Department of Tourism, Government of Uttar Pradesh; Statistics of Tourists Visits at Important Historical Places/Monuments in Uttar Pradesh (2014-2017/2015-2018), Department of Tourism, Government of Uttar Pradesh; Statistical Abstract Uttar Pradesh (Multiple Years), Economic and Statistic Division, State Planning Institute, Planning Department, Uttar Pradesh; Uttar Pradesh Statistical Diary (2019, 2022); Tourism Data Dashboard, UN World Tourism Organization (2018, 2019); Annual Research Highlights, World Travel and Tourism Council (WTTC, 2020); and Economic Survey of India and Uttar Pradesh Tourism Policy, 2018. The paper calculates the annual growth rate of multiple years and the share of tourists in each region to the total tourists influx in the country.

Results and Discussions

Tourism has a spatial and cultural difference in the way it takes place in different societies and regions. It is often known as the temporary movement of people to destinations outside their normal place of work and residence. India has a long tradition of people moving for various pilgrimage and religious sites. Thus, travel and tourism have been a part of Indian tradition and culture. The modern mass tourism is more organized and it adds significantly to the economic development.

The tourism industry in India plays a significant role in significant economic multiplier and it has more potential for the growth in employment sector. At a broader level "India accounts for a majority of South Asia's travel and tourism gross domestic product (GDP) and has also been the preferred destination for tourists from within the region" (Sinha and Sharma, 2020). The foreign exchange earnings from tourism in 2010 were Rs. 648.89 billion as compared to Rs.549.60 billion during 2009. The approach paper of the Twelfth Five Year Plan (2012-17) of the Planning Commission of India highlighted the need to adopt "proper tourism" to increase net benefits to the poor and ensure that tourism growth contributes to poverty reduction. India is divided into five tourist zones: northern, southern, eastern, western and central. Under the Ancient Monuments and Archaeology Sites and Remains Act, of 1958, the Archaeological Survey of India has declared three thousand six hundred and seventy-five monuments or sites to be of national importance which includes twenty-one properties that are inscribed as World Heritage Sites by UNESCO. By 2015, there were thirty World Heritage Sites in India, six were natural and the rest of the others are cultural wonders. The country India is endowed with rich physical landscapes including mountains, beaches, deserts, mangroves, rivers etc.

The celebration of fairs, festivals and manifold religious fabric gives support to wider tourism in India. In India, more attention is now being paid to the protection and conservation of the monuments including their cultural heritage such as performing art, visual art, festivals, languages, folk art and handicrafts. The major schemes in India are being aimed at Product/Infrastructure and Destination Development at certain places of tourism importance. Thus, to make these places as most tourist attractions, major redevelopment works and rejuvenations are being carried out at such heritage places of social, cultural and spiritual importance. Studies suggested that heritage can act as an important holistic development tool for the overall community development in India (see, Sharma and Sharma, 2017). The Uttar Pradesh Tourism Policy has the mission "to drive a sense of inclusive tourism development in the local community and make optimum use of tourism experiences across vibrant cities, attractions, nature, wildlife, adventure, food, heritage, religion and culture of state" (2018). Analysis of trends of domestic tourism in India over the past years offers an insight into the flow. In 2005, 392.04 million domestic tourists visited India which increased to 747.70 million in 2010. The number of domestic tourists further increased to 1431.97 million by 2015. It reached 2321.98 million in 2019. In terms of annual growth rate, it was 17.96% in 2006. It showed a decline in 2007 being at 13.90% and further declined to 6.90% percent by 2008.

However, there was a drastic growth of 18.79% in 2009, but it declined to 11.8% in 2010. Then there was a sudden growth in 2011 at 15.63% and it further grew to 20.88% growth rate in 2012. Then afterwards there has been a decline over the next year. The years 2014 and 2016 showed an increase in annual growth rates. It declined later in 2015 and grew in 2018. There was a drastic fall in growth rate in 2017 when it dropped to 2.61%. However, the year 2019 showed an annual growth rate of 25.26%. Thus, one can see that the trends of domestic tourist growth in India have been erratic during this period. The trend of foreign tourist arrival in India is similarly encouraging. The number of foreign tourists in India increased from 9.94 million in 2005 to 17.91 million in 2010. The period from 2005 to 2009 registered a declining trend in the annual growth rate of foreign tourists as the annual growth rate of 18.07% in 2006 declined to -0.06% in 2009. In 2010, the annual tourism growth rate bounced back to 24.62%. This further declined to -6.33% in 2012. The number of tourists visiting the country increased to 23.32 million in 2015. In 2019, this further increased to 31.40million. Though there was an overall growth in the number of tourists visiting the country, the annual growth rate pattern is very irregular.

The annual growth rate of domestic tourists in Empowered Action Group (EAG) states of India. The annual growth rate (AGR) of domestic tourists in Assam was 5.2% in 2010 which declined to 3.3% in 2014. It anyhow increased to 13.75% in 2015 but it again dropped to -6.03% in 2016. The growth rate further improved to 15.65% in 2019. The state of Bihar had an annual growth rate of tourism at -0.51% in 2011, which increased to 24.33% in 2015. The domestic AGR of Bihar reached 1.1% in 2019. Chhattisgarh had a domestic AGR of 13.8% in 2011, which declined to 5% in 2012. It drastically increased to 51.64% in 2013. It again declined sharply to 7.4% in 2014 and -25.16% in 2015. It dropped to -10.48% in 2019. The domestic AGR of Jharkhand was highest being at 62.97% in 2014. It declined and reached to 0.49% in 2019. Madhya Pradesh had the highest domestic AGR in 2010 with 64.8% of the domestic Annual Growth Rate. The domestic AGR of Odisha remained almost the same till it drastically dropped to 0.65% in 2019. Rajasthan had the lowest domestic AGR of -0.1% in 2010. It depicted an erratic pattern and reached 3.95% in 2019. Uttarakhand had a domestic AGR of 37.7% in 2010. It witnessed the lowest of ten years in 2013 with a domestic AGR of -25.67%. A gradual rise was reported later and it reached 5.55% in 2019. The annual growth rate of foreign tourists in Empowered Action Group (EAG) states of India. Overall, the growth rate of foreign tourists in EAG states has been fluctuating over the

years in the country. The Foreign AGR of Assam in 2010 was 1.4% which declined to -48.69% in 2016. It witnessed a sharp increase of 69.33% and 72.38% in 2018 and 2019 respectively.

The state of Bihar has a record of the highest foreign AGR of 52.97% in 2011 from 50.3% in 2010 and it declined to -30.18% in 2013. It grew by 11.36% in 2015. Its annual growth rate declined and reached 0.48% in 2019. In Chhattisgarh, the annual growth rate of foreign tourist arrivals has been showing signs of fluctuation over the years from 2010 onwards. The highest foreign growth rate of Chhattisgarh was recorded at 114.88% in 2018, which dropped sharply to rate of -52.66% in 2019. Jharkhand had the highest jump in foreign tourist growth rate at 361.72% in 2011 which declined again in the next two years. It suddenly jumped to 236.41% in 2014. It further went down and reached 0.14% in 2019. Madhya Pradesh had a lower growth all through the past years from 2010 onwards. The State's foreign tourist growth rate was lowest at -13.8% in 2016 and again it grew at -12.66% in 2019. Odisha had a lower growth rate in 2010 and 2011 compared to the EAG average. It showed signs of fluctuations over the next few years. The highest foreign tourist arrival growth in Odisha was recorded at 31% in 2017 and it again declined and grew at 3.89% in 2019. Uttarakhand in 2010 had an annual growth rate of 19.5%. Then afterwards it declined while growing at -2.05%, -0.08%, -21.57% in 2011, 2012 and 2013 respectively. It jumped to 14.2% in 2017 but declined later to 13.16% and 0.63% in 2018 and 2019 respectively. The state of Uttar Pradesh has not seen an impressive growth rate in foreign tourist arrivals in the initial years since 2010. It jumped in 2014 and grew at 41.63%, however, it declined in later years It again in 2017 grew at a 12.7% rate higher than the EAG average and declined later. Its growth rate was reported at 25.51% in 2019, again it was higher than the EAG average.

Heritage-Religious Tourism in Uttar Pradesh

Uttar Pradesh is popular for many historical monuments such as the Taj Mahal, Fatehpur Sikri, Dhamek Stupa, Bada Imambara etc. and also religious and spiritual places such as Varanasi, Prayagraj, Ayodhya, Kushinagar, Vrindavan, Mathura and others. Agra is one of the most populous cities in Uttar Pradesh and a major tourist destination because of its many Mughal-era buildings, most notably the Taj Mahal (one of the Seven Wonders of the World), Agra Fort and Fatehpur Sikri. It is included in the Golden Triangle tourist circuit, along with Delhi and Jaipur. Lucknow is a multicultural city that flourished as a North Indian cultural and artistic hub,

and the seat of power of Nawabs in the 18th and 19th centuries. Shravasti, located near the West Rapti River, is closely associated with the life of Gautama Buddha who is believed to have spent 24 Chaturmases here. Kushinagar is an important Buddhist pilgrimage site, where it is believed that Gautama Buddha attained Parinirvana after his death. The followers of Buddhism, especially from Asian countries, wish to visit this place at least once in their lifetime. Of course, Varanasi or Kashi situated on the banks of the Ganges is a major religious hub in India. It is the holiest of the seven sacred cities (Sapta Puri) in Hinduism and Jainism and played an important role in the development of Buddhism. Vindhyanchal is a renowned religious city in Mirzapur District. The city is a Hindu pilgrimage site with the Vindhyavasini Devi temple situated on the banks of the holy river Ganga. It is one of the most revered Shakti Peeths of the presiding deity, Vindhyavasini Devi. There are also physical and natural scenic attractions including the Ganga, the Yamuna, Dudhwa National Park, Chandraprabha Wildlife Sanctuary and other places. Unique archaeological sites such as Sinauli and Sarnath are also located in the state. They all offer a plethora of options to tourists who visit the state and attract tourists of domestic and foreign origin as well.

Table-1 shows the domestic tourist arrivals pattern in Uttar Pradesh. The domestic tourism arrival has seen an increasing trend in Uttar Pradesh. In 2005, 95.44 million domestic tourists visited Uttar Pradesh which further increased to 144.75 million in 2010The number of domestic tourists kept growing and reached 204.88 million in 2015 and 535.85 million in 2019. The annual growth rate of domestic tourists has been an erratic trend. The annual growth rate of domestic tourists was 8% in 2005, which increased in the next few years but came to 7.36% in 2010. Since then, the annual growth rate gradually accelerated over the next few years and highest ever recorded in 2013. The lowest growth rate was in 2014 at -19.3%. It reached to 12.07% in 2015. Further, it declined and reached 3.33% in 2019. In terms of the share of the state in total domestic tourists in India, it has been remarkable from 2005 to 2010, later showing signs of declining share. It was reported 23.08% in year 2019. Foreign tourism in Uttar Pradesh witnessed a different trend. In 2005, some 1.17 million foreign tourists visited Uttar Pradesh. The number of foreign tourists visiting the state increased to 1.67 million in 2010 and further increased to 3.10 million in 2015. The number of foreign tourists increased to 4.74 million in 2019. The annual growth rate was recorded at 13.24% in 2005. The lowest growth rate was in 2009 being at -3.71%/. It jumped and reached at 9.67% in 2010. It has grown over the next few years, the highest being recorded in 2014, it came to

Table-1: Share of Domestic and Foreign Tourists of Uttar Pradesh in India

Years	Domestic Tourists (%)	Foreign Tourists (%)
2005	24.34	11.81
2006	22.82	11.31
2007	22.07	11.49
2008	22.17	11.2
2009	20.16	10.79
2010	19.36	9.67
2011	17.98	9.68
2012	16.11	10.92
2013	19.83	10.3
2014	14.25	13.03
2015	14.31	13.31
2016	13.11	12.77
2017	14.12	13.23
2018	15.38	13.1
2019	23.08	15.11
2020	14.11	12.42
2021	16.19	4.24
2022	18.37	7.56

Source: India Tourism Statistics, Ministry of Tourism, Govt. of India

6.68% in 2015. It again showed fluctuation in the next few years reaching 12.65% in 2016. It came down to 6.31% in 2018 and a sudden jump was recorded in 2019 where it grew to 25.51%. Whereas the share of the state in overall foreign tourists in the country is concerned, it has been somehow constant over the years since 2005 onwards and showed a declining trend in 2010 and 2011. It further maintained its course and gradually bounced back over the next years and had 15.11% in 2019. The COVID-19 pandemic and subsequent lockdowns impacted tourism in the country. The number of domestic tourists dropped to 86.12 million registering a sharp decline of -83.93% in 2020. Similarly, foreign tourists also dropped by -81.22% to 0.89 million in this. The tourism industry showed resilience and tourism started growing again in 2021 with an increase of 27.89% in 2021. Although,

due to air restrictions, foreign tourism dropped further by -94.98% in 2021. In the year 2022 they witnessed rapid growth in terms of both domestic and foreign tourism. In Uttar Pradesh, the tourist destinations are grouped into nine Regional Tourist Office (RTO) Zones. These RTO zones include Agra, Jhansi, Bareilly, Prayagraj, Varanasi, Lucknow, Meerut, Ayodhya and Gorakhpur. Thus, the trend of tourism in all RTO zones over the past few years has been analyzed. The percentage share of domestic tourists in various RTO zones of Uttar Pradesh. Here Agra zone received the highest number of domestic tourists in Uttar Pradesh. The percentage share of domestic tourists in the Agra RTO zone was 19.8% in 2013, which increased to 25.27% in 2014 and 29.55% in 2015. Afterwards, the zone has shown signs of decline having come down to 29.09%, 28.16%, 26.82% and 15.20% in 2016, 2017, 2018 and 2019 respectively. Agra zone is followed by Prayagraj RTO zone with a 37.7% share in 2013 in total domestic tourists in Uttar Pradesh. It declined to 20.08% in 2014 and remained almost the same at 20.08%, 19.9%, 19.3% and 17.3% in 2015,2015,2017 and 2018 respectively. It increased to 53.8% in 2019. The next zone which received a higher share of domestic tourists is Ayodhya followed by Meerut, Jhansi and then Varanasi zones. Fig. 1 depicts the percentage share of domestic tourists in various RTO zones of Uttar Pradesh. Here Agra zone received the highest number of domestic tourists in Uttar Pradesh. The percentage share of domestic tourists in the Agra RTO zone was 19.8% in 2013, which increased to 25.27% in 2014 and 29.55% in 2015. Afterwards, the zone has shown signs of decline having come down to 29.09%, 28.16%, 26.82% and 15.20% in 2016, 2017, 2018 and 2019 respectively. Agra zone is followed by Prayagraj RTO zone with a 37.7% share in 2013 in total domestic tourists in Uttar Pradesh. It declined to 20.08% in 2014 and remained almost the same at 20.08%, 19.9%, 19.3% and 17.3% in 2015,2015,2017 and 2018 respectively.

It increased to 53.8% in 2019. The next zone which received a higher share of domestic tourists is Ayodhya followed by Meerut, Jhansi and then Varanasi zones (Fig. 1). It is quite clear here that a major share of foreign tourists visited the Agra and Varanasi zones in Uttar Pradesh. This trend is followed by Prayagraj and others. In 2013, 48.4% of total foreign tourists visiting the state of Uttar Pradesh visited Agra. It further increased to 50.7% in 2014, and 53.04% in 2015. It declined to 51.16% in 2016 but again bounced back and increased to 53.63% in 2017. However, it declined later to 53.4% in 2018 and 43.21% in 2019. This zone was followed by Varanasi which had 20.77% foreign tourist's share in 2013. It further jumped to 23.38% in 2014. The share of Varanasi in total foreign tourists

visiting Uttar Pradesh remained at 22.84%, 23.45%, 22.06% and 21.30% in 2015, 2016, 2017 and 2018 respectively. Further, it declined by the year 2019. This zone is followed by Gorakhpur, Ayodhya, Jhansi, Prayagraj, Lucknow and the remaining zones. Prayagraj occupies a unique position in the tourist flow pattern in the state. Prayagraj zone received a higher share of foreign tourists in 2013, which was 12.6%. Afterwards, it slipped down more than fifty percent of this share reaching 4.1% in 2014, 4.19% in 2015, 4.1% in 2016, 3.7% in 2017 and 4.5% in 2018. However, with a congregation of Kumbh, the foreign tourist share shot up again and increased to 25.19% in 2019.

Growth Pattern of Tourism in Eastern Uttar Pradesh

The state of Uttar Pradesh has been divided into four sub-regions- Western Uttar Pradesh, Central Uttar Pradesh, Bundelkhand and Eastern Uttar Pradesh. The Eastern Uttar Pradesh sub-region is also known as 'Purvanchal'. The eastern portion comprises of Allahabad, Ambedkar Nagar, Amethi, Azamgarh, Ayodhya, Bahraich, Ballia, Balrampur, Basti, Chandauli, Deoria, Ghazipur, Gonda, Gorakhpur, Jaunpur, Kaushambi, Kushinagar, Maharajganj, Mau, Mirzapur, Pratapgarh, Sant Kabir Nagar, Sant Ravi Das Nagar, Shravasti, Siddharth Nagar, Sonbhadra, Sultanpur, and Varanasi. These RTO zones include Varanasi, Prayagraj, Gorakhpur and Ayodhya. At present, Eastern Uttar Pradesh has eight prominent tourist destinations where both domestic/local and foreign tourists visit to see and experience a blend of historical, cultural and heritage places. Here, Varanasi is believed to be the one of oldest cities- the ancient- of the world. Since her origin, the city has grown in the rich tradition of Hindufold. Now, it has a unique amalgamation of several religions such as Hinduism, Buddhism Jainism and other cultures. The city is famous for its region-cultural significance. The city is well known for the great Ganga Ghats (river fronts) and is known as the "City of Salvation". (Table-2)

The Lord Buddha gave his first sermon at Sarnath, a place located close to the city of Varanasi. The Ayodhya is located at the bank of river Sarayu and it is believed to be the birthplace of Lord Rama. The Prayagraj is considered as a holy city due to the confluence of sacred rivers such as Ganga, Yamuna and Saraswati. Gorakhpur is well known for the Gorakhnath Temple. Shravasti is believed to be where the Buddha taught many of his Suttas (sermons). Buddha attained his mahaparinirvana (salvation) in Kushinagar located in the region. Kaushambi is an important Buddhist tourist destination in Eastern Uttar Pradesh. Sant Kabir Nagar has a blend of natural, cultural and historical places to visit and attracts tourists. Table-2 shows the annual growth rate of tourists to the important tourist destinations

Table-2: Annual Growth Rate (%) of Tourist Destinations of Eastern Uttar Pradesh

Years	Varanasi	Ayodhya	Prayagraj	Gorakhpur	Shrawasti	Kushinagar	Kaushambi	Sant Kabir Nagar
2001	2.89	16.64	23.14	-0.7	-2.33	-2	32.61	6.25

Note: Data is not available for a given destination is shown by symbol.

located in Eastern Uttar Pradesh. Some of these tourist places have witnessed the highest record of annual growth rates over the past two decades (Fig. 1). Ayodhya had an unusual growth, the highest ever, in 2009. Prayagraj recorded first highest annual growth rate (143.07%) in 203 and second highest (536.46%), ever recorded, recorded in 2019. Gorakhpur had a higher annual growth rate (718.09%) in 2006 after 2004 when it was 28.86%. Shravasti experienced the highest annual growth rate (338.76%) in 2018. Kushinagar had a high growth rate (873.54%) in 2017. Sant Kabir Nagar had a higher annual growth rate of tourists in the year 2006. These changes in some years are the result of many initiatives of state governments such as organizing fairs or other cultural and religious activities.

Development Policy, Planning and Recent Initiatives

Eastern Uttar Pradesh has seen a kind of revival of several historical, religious and heritage sites in the context of their religious and touristic importance in recent years. The political dynamics of the nation over the last few years have focused on that "destroying the existing structures is not the way but the emphasis should be on rejuvenation and preservation. This should be done in accordance with the requirements of modern times" (Kamal Sandesh, 2022). Primarily, Varanasi, Ayodhya, Prayagraj, Gorakhpur, Shravasti, Kushinagar, Kaushambi and Sant Kabir Nagar dominate the tourist landscape of the region. Efforts are being made towards several other places to be developed in the region. Of the many places, only a small number of places have been figuring in the tourist-destination profile of the state. There are many more places, found in almost every district, as identified by the Department of Tourism of Uttar Pradesh (see, Statistical Diary 2020, Annexure 24), where future tourism development can be directed in the eastern region. Initially, the state policy for tourism development is reflected in Uttar Pradesh's industrial policy. The two main objectives that came to light were: increasing employment in the region; and targeting high growth. In this context, there was a realization that the service sector must be promoted for the industrial and economic growth of the state. It was here that mention of imperatives for the preservation of the environment and cultural heritage as well as the need to promote specific geographic areas/corridors are highlighted (Uttar Pradesh Development Report, Vol.2, 2007).

A report on "20 Years Perspective Plans for Uttar Pradesh" by the Department of Tourism, Government of India (2002) highlighted the corollary objectives which focused on: i) promoting tourism development in harmony with local community involvement and employment, ii) protecting, preserve and conserve the monuments that a testimony to the past and are to be bequeathed to future generations; and

iii) to promote the highest possible standards of cleanliness, sanitation, and landscaping elegance. The report listed the following hubs of tourism in the state of Uttar Pradesh: Varanasi, Jhansi, Agra, Lucknow, and Greater Noida. The fact is that Uttar Pradesh has tremendous potential to attract both foreign and domestic tourists. The government of Uttar Pradesh has enacted Tourism Policy 2018 for the holistic development of tourism in the state. It aims to achieve the target "to become the most preferred tourist destination of the country by 2023" (Uttar Pradesh Tourism Policy 2018). This policy laid down six pillars to successfully achieve the targets of the policy: Strengthening Tourism Infrastructure; Promoting Investment and Employment Generation; Augmenting Brand Uttar Pradesh; Focus on Religious/Spiritual Tourism; Promoting Theme Based Tourism; and Sustainable Tourism through Community growth and upgradation of local skills.

The state has taken key steps to ensure better connectivity of districts and tourist places in the eastern region. Recently, Kushinagar International Airport has become operational, which will connect many countries especially South Asian and South East Asian countries where Buddhism is prominent. Now two international airports are functional in Eastern Uttar Pradesh in Varanasi and Kushinagar. Along with Taj Mahotsav at Agra, various events such as Rangotsav at Barsana, Dev Deepawali at Varanasi and Deepotsav at Ayodhya have contributed to transforming the state's image as an attractive tourist destination for both religious and leisure tourism. Religious and spiritual tourism contributes a prominent part of tourism in the state. Strengthening and upgradation of civic amenities, the establishment of shrine boards to manage religious places, creation of accommodation facilities has been the aims. The centrally launched schemes such as HRIDAY (Heritage City Development and Augmentation Yojana) under the Ministry of Urban Development, Government of India, and the objectives are heritage conservation, beautification, cleanliness, safety, accessibility and service delivery. Another scheme is the PRASAD (Pilgrimage Rejuvenation and Spiritual Augmentation Drive) scheme under the Ministry of Tourism, Government of India. It aims to integrate pilgrimage destinations in a prioritized, planned and sustainable manner to provide a complete religious tourism experience. There are two cities in Uttar Pradesh under these schemes: Mathura and Varanasi.

The former scheme focuses on infrastructure that preserves the heritage character, while the latter goes beyond this to include vocational training programmes and other things that make up the tourism ecosystem. The Kashi Vishwanath complex in the city of Varanasi has been undergoing an unprecedented transformation and

the site is being connected to the river Ganges. The project comprises of Shri Kashi Vishwanath Dham, Manikarnika Ghat and its Beatification. The operation of the project will provide value addition to the existing infrastructure, as due to the development of the project, the commercial facilities such as public transport, water supply, telecommunications, power lines, road maintenance etc. all to be upgraded. The growth of domestic tourism hugely depends on pilgrimage tourism. In Uttar Pradesh, heritage tourist circuits are being developed which would lead to holistic development of all the places sharing cultural or spiritual importance. Some of these tourist circuits in the state and the Eastern region are: i) the Buddhist Circuit connecting Kapilvastu, Kaushambi, Kushinagar, Sankisa, Sarnath, and Sravasti; ii) The Heritage Arch connecting Agra, Lucknow and Varanasi; iii) Braj Circuit connecting Agra, Vrindavan and Mathura; iv) Awadh Circuit connecting Lucknow, Devasharif, Naimisharanya, Ayodhya, Faizabad; v) Vindhya Varanasi Circuit connecting Varanasi, Chunar and Vindhyanchal; vi) Ramayana Circuit connecting Ayodhya with important places related with Lord Ram; vii) Bundelkhand Circuit connecting Bithoor, Chitrakoot, Jhansi, Kalinjar and Mahoba; viii) Mahabharat Circuit connecting Hastinapur, Kampilya, Barnava, Mathura and Gonds; ix) The Aadhyatmic Circuit connecting Gorakhpur, Balrampur, Ghazipur, Goriya and Sant Ravidas Nagar; and x) The Sufi/Kabir Circuit connecting Amethi, Maghar, Salim Chishti Dargah and Barabanki (see, Uttar Pradesh: A conglomeration of Culture, Religious and Heritage Tourism, FICCI-MRSS, 2018). Beautification of places has also been on the agenda of the government to promote tourism.

The new tourism policy also takes this into account and aims to promote theme-based tourism such as eco-tourism, agri-tourism, caravan tourism, adventure tourism, sports tourism, rural tourism, etc. In this way, the state aims to create a 'Brand Uttar Pradesh'. Uttar Pradesh is rich in handicrafts and handlooms. Gorakhpur's Terracotta, Varanasi's Silk, Bhadohi's Carpet, Agra's Zardoji, Khurja's Pottery, Firozabad's bangles, etc. have global demand and repute. The 'Hunar Se Rojgar' scheme of the Government of India and the 'One District One Product' initiative of the Uttar Pradesh government a medium to promote crafts and handloom in the tourism sector. The new Tourism Policy advances the idea of 'Weekend Tourism', under which potential tourist spots have been identified, where people living in and around the area can visit the place. These tourist sites can also act as major tourist attractions for foreign tourists. These weekend tourist spots have only been identified for a few districts. It is essential to identify such places in all the districts of Uttar Pradesh and connect these locations with major tourist

destinations. The Pro-Poor Tourism Growth Project of Uttar Pradesh is projected to offer far-reaching social, economic and environmental benefits at local and regional levels. The project aims to meet the expectations of both low and high-spending domestic and foreign tourists visiting each such destination by enhancing their overall experience. (Table-3)

Table-3: Features of Drivers-Pressures-State-Impacts-Responses Framework

Elements	Major Features
Drivers	Tourist attendance, urban traffic, hospitality structures, urbanization, status of environment etc.
Pressures	Air quality, production of urban solid waste, use of land, presence of tourists in protected areas etc.
State	The concentration of pollutants in the air, change of land use, state of the local host community tourist satisfaction etc.
Impacts	Adverse impact on heritage structures, local host community, profile of tourism industry etc.
Response	Awareness about sustainable tourism activities, promoting eco-friendly transport, promoting eco-tourism activities etc.

Source: EEA 1998: Guidelines for Data Collection and Processing, EU State of Environment Report

Emerging Challenges and Prospect of Sustainable Tourism

There are many grey areas which need to be identified and improved for the holistic development of tourism in the state. The major challenge is still the connectivity issue and availability of transport networks. The tourist concentration is only in a few districts and geographical regions of the state, other tourist places remain the least connected. The dedicated heritage or tourist corridors can also be made to cater for the specific needs of tourists and provide a seamless experience. The important tourist sports need to be connected by other important but now so well-known tourist spots of the state. Heritage tourism is usually promoted around tangible heritage and monumental sites. Though monument protection and conservation are important, the promotion and protection of intangible heritage such as folk art, dance and music forms, traditions and customs are equally important. Special attention should be paid towards intangible heritage also because if they are not supported, they may not be passed on to coming generations.

The intangible heritage is a unique feature of the place and can act as a major tourist attraction. Skill upgradation of people involved in the formal hospitality sector should be done periodically. The government can provide subsidies and incentives for opening accommodation facilities at tourist places. The government has planned to convert heritage buildings into hotels. This can also help to attract tourists but while doing this, the conservation of these heritage buildings must be assured. Uttar Pradesh is rich in water resources. The rivers can be used to promote tourism by promoting water transport. State Waterways can be developed on the theme of National Waterways. Identifying the opportunity and feasibility of water-based adventure sports and their promotion can help boost tourism in the region (Table-3). The feasibility of connecting various cities located at the bank of rivers by river cruise service should be analyzed. These steps can help to strengthen the position of Uttar Pradesh in the tourism sector (Jaiswal, 2021). To make tourism more sustainable and integrated in Uttar Pradesh, the DPSIR framework (European Environment Agency, 1999) can play an important and strategic part in tourism development and management. The tourism industry thrives on the kind of environmental, ecological and social-cultural conditions present at tourist destinations. Thus, an assessment of physical, accommodation, environmental and economic carrying capacity is inevitable for further planning of tourist destinations.

Conclusion

Study shows that tourism in India is growing in the terms of arrival of domestic and foreign tourists. The growth rate pattern indicates an erratic fluctuation in the country and state of Uttar Pradesh as well. Tourism and its growth rate in Empowered Action Group (EAG) states are relatively promising and at certain times it is found higher as compared to that of the country. This indicates the fact these states have immense opportunities in the tourism sector. Among them all, the state of Uttar Pradesh offers a hybrid experience to tourists. However, a few tourist destinations and places dominate the tourism flow in the state. Only a few places in the Eastern part of Uttar Pradesh have a cultural, historical, and heritage edge in tourism over the other places. Only a few of them are hubs for religious and spiritual tourism and attract a significant number of domestic and foreign tourist arrivals in the country and state. There is a need to work in the direction of making a shift from the conventional tourism development approach towards more inclusive tourism development in the state. This will create more economic opportunities in tourism in

the state and eastern region. For comprehensive planning for tourism development, there are certain factors such as a sense of security, affordable accommodation, better connectivity perception building etc. should be given place in further tourism development planning.

SPATIAL ANALYSIS OF REGIONAL DISPARITY IN INDIA BASED ON NSSO 78TH ROUND DATA ON MULTIPLE INDICATORS OF DEVELOPMENT

Dr. Chhering Tandup and Sheezan Khursheed Kichloo

Abstract

Understanding regional disparities is crucial for addressing social and environmental factors that contribute to inequality and poverty. The study aims to analyze regional disparities in India using secondary data from the 78th round of the National Sample Survey (NSS) Multiple Indicator Survey (MIS) conducted in 2020–2021. The study has focused on state-wise disparities across multiple indicators as well as comparing disparities in urban and rural areas. The coefficient of correlation matrix has been used to determine the relationship between different socio-economic development indicators in both rural and urban areas. The Kandell Ranking Coefficient Method is also used to identify high-, medium-, and low-developed states or union territories based on socio-economic development indicators. GIS mapping and spatial analysis have been utilized to visualize and investigate regional disparities in India through a mixed-method approach.

Introduction

India is a country with vast diversities in terms of geography, culture, and economic development. Regional disparities refer to the differences in economic growth, social development, infrastructure, and living standards in different regions of the country. These disparities arise due to various factors, such as historical legacies, natural resource distributions, government policies, and infrastructure. The regional disparities in India are pronounced and can be seen in various aspects. Firstly, there are significant variations in economic growth and development between regions. States like Maharashtra, Tamil Nadu, Gujarat, and Karnataka have seen significant economic growth, while many states in the eastern and northeastern regions are still struggling with poverty and underdevelopment. Secondly, there are differences in social development indicators such as education, health, and gender equality. Southern states like Kerala and Tamil Nadu have high literacy rates and

good health indicators, while many states in North India have poor literacy rates and health indicators. Thirdly, there are also infrastructure disparities between regions. Cities like Delhi, Mumbai, and Bangalore have modern infrastructure and good connectivity, while smaller cities and towns in rural areas lack basic infrastructure like roads, electricity, and water supply. The reasons for regional disparities can be attributed to various factors. One of the major factor is the historic legacy of colonialism, which led to the concentration of economic and administrative power in certain regions. Additionally, natural resources like minerals and fertile land are unevenly distributed across the country, leading to disparities in economic growth. Sastry and Tripathi (2013) argue that MIS is an essential tool for data collection and analysis in the field of health research. Seneviratne, S. I., & Wickramasinghe, R. (2018). Regional disparities in Sri Lanka: A multidimensional perspective. Journal of Development Studies, 54(1), 1–16. This study uses MIS to analyze regional disparities in Sri Lanka across various dimensions, including economic, social, and environmental indicators. The authors highlight the importance of addressing social and environmental factors in reducing regional disparities. Kabeer, N., & Mahmud, S. (2019).

Study Region

India is surrounded by Bay of Bengal in the east, the Arabian Sea in the west, and the Indian Ocean to the south. Lying entirely in the Northern Hemisphere, the Country extends between 8° 4' and 37° 6' latitudes north of the Equator, and 68° 7' and 97° 25' longitudes east of it India is a vast and diverse country with a population of over 1.3 billion people. The country is located in the Indian subcontinent and is bordered by Pakistan, China, Nepal, Bhutan, Bangladesh, and Myanmar. The study region of India is vast and includes various geographical regions such as the Himalayas in the north, the Gangetic Plain in the north and northeast, the Deccan Plateau in the center, and the coastal regions in the south, east, and west. The climate varies significantly across these regions, with extreme temperatures and weather conditions in some areas. The economy of India is rapidly growing and is the fifth-largest economy in the world by nominal GDP and the third-largest by purchasing power parity (PPP). The country has a diverse mix of industries, including agriculture, manufacturing, services, and technology. The study region of India is significant due to its large population, rapid economic growth, and diverse geography, making it an important area for research in various fields such as economics, geography, politics, and culture.

Objectives

To examine regional disparities and analyze state and UT wise level of development in India based on NSSO 78th round data on multi-indicator basis at the rural and urban level for 2020-2021.

Database and Methodology

The present study relies solely on secondary data. In this dissertation, the secondary source of data was acquired from the 78th round of the National Sample Survey (NSS) Multiple Indicator Survey, which was conducted during the period of 2020–2021. The data included a wide range of variables and indicators related to socio-economic factors such as income, education, employment, health, etc. The main indicators are access to piped water, access to improved sources of drinking water, access to latrine, clean fuel as the primary source of cooking, heating, and lighting, the percentage of rural households reporting the availability of all-weather roads within 2 km from their place of residence, public transport facilities within 500 m from their place of residence, access to bank accounts, financial institutions, or mobile money services, and access to mass media. Indicators were categorized into rural and urban areas to compare disparities in different environments. The technique of analysis of the coefficient of correlation matrix has been used to determine the relationship between different socio-economic development indicators in both rural and urban areas. This technique has been used as a tool for quantifying the relationship between variables and has been an important part of the methodology used in this study. The Kandell Ranking Coefficient Method was used to identify high-, medium-, and low-developed states or union territories based on socio-economic development indicators. ArcGIS 10.8 software was utilized to create maps and visualize data, while MS Excel was used for charting and analysis.

Results and Discussion

Table-1 provides data on the percentage of rural and urban persons having access to an improved source of drinking water for each state or UT of India. The data highlights the regional disparity between rural and urban areas among different states and UTs in terms of access to clean and safe drinking water.

Rural Areas

The percentage of rural households with access to an improved source of drinking water ranges from as low as 54.4% in Kerala to as high as 99.3% in Uttar Pradesh. States like Kerala, Manipur, Nagaland, and Jharkhand have relatively low

percentages, indicating limited access to safe and clean drinking water in rural areas. States like Uttar Pradesh, Bihar, and Haryana have high percentages, indicating better access to clean drinking water in rural areas. (Fig 1)

Urban Areas

The percentage of urban households with access to an improved source of drinking water ranges from 55.9% in Kerala to 100% in many states and UTs such as Delhi, Chandigarh, Daman & Diu, and Lakshadweep. Urban areas generally have a higher percentage of households with access to improved sources of drinking water compared to rural areas. States like Kerala and Tamil Nadu have relatively low percentages in terms of urban access to clean drinking water, indicating a need to improve access in urban areas. Overall, the data demonstrates a significant disparity in access to clean and safe drinking water between rural and urban areas in different states and UTs of India. While some states have achieved relatively high percentages of access to clean drinking water, many states and UTs still face significant challenges in this regard. (Fig. 1)

Table-1: Percentage of Rural Access for Rural and Urban Population and Improved Source of Drinking Water

State/UT	Rural	Urban	All
Andhra Pradesh	96.8	99.2	97.5
Arunachal Pradesh	97.9	100.0	98.3
Assam	90.8	97.8	91.6
Bihar	99.2	99.9	99.3
Chhattisgarh	94.8	99.8	96.0
Delhi	100.0	100.0	100.0
Goa	99.6	100.0	99.8
Gujarat	94.8	100.0	98.0
Haryana	100.0	99.8	99.9
Himachal Pradesh	98.0	99.8	98.2
Jharkhand	86.5	97.2	88.8
Karnataka	95.6	98.3	96.6
Kerala	54.4	55.9	55.2
Madhya Pradesh	88.4	99.5	91.4

Sources: NSS Report No. 589(78th Round 2020-2021): Multiple Indicator Survey in India

Sanitation Facility

The data highlights significant regional disparities in terms of access to sanitation facilities across different states and UTs.

Rural Areas

The percentage of rural households reporting access to a latrine ranges from as low as 58.7% in Jharkhand to 100% in Kerala, Manipur, Mizoram, and Nagaland.

States like Bihar, Odisha, and Rajasthan have a relatively low percentage of rural households with access to a latrine, reflecting inadequate sanitation facilities in these areas. States like Arunachal Pradesh, Assam, Himachal Pradesh, and Sikkim have relatively high percentages of rural households with access to a latrine, indicating better access to sanitation facilities in these areas. The all-India percentage of rural households reporting access to latrines is 78.7%.

Urban Areas

The percentage of urban households reporting access to a latrine range from 91.9% in Jharkhand to 100% in many states and UTs such as Arunachal Pradesh, Mizoram, Nagaland, and Sikkim. Urban areas generally have a higher percentage of households with access to a latrine than rural areas, reflecting better sanitation facilities in urban areas. Some states, such as Odisha and Tamil Nadu, have relatively low percentages of urban households with access to a latrine, indicating a need to improve access to sanitation facilities in these areas. The all-India percentage of urban households reporting access to latrines is 97.1%. Overall, the data shows that there are significant regional disparities in terms of access to sanitation facilities in India, particularly in rural areas. A lower percentage of rural households have access to a latrine compared to urban households.

Use of Clean Fuel

The national average for households using clean fuel as a primary source of energy is 16.4% in rural areas and 75.9% in urban areas. There is a wide variation in the percentage of households using clean fuel across different states and union territories. For instance, in Delhi, 91.4% of rural households and 82.6% of urban households use clean fuel. On the other hand, in Nagaland, only 0.8% of rural households and 24% of urban households use clean fuel. States and union territories with higher urbanization levels generally have higher percentages of households using clean fuel, with the exception of Mizoram, where 80.9% of rural households use clean fuel, compared to 13.9% of urban households. Puducherry has the highest percentage of urban households using clean fuel at 93.5%, and Sikkim has the highest percentage of rural households using clean fuel at 25.6%. Jharkhand has the lowest percentage of rural households using clean fuel, at only 3.8%. Overall, the data suggests that there is a significant disparity in access to clean fuel across various parts of India, with rural areas and some states having much lower usage rates.

Facilities for Connectivity

Overall, 92.5% of rural households in India have access to all-weather roads within 2 km from their place of living, while 89.6% of rural households have access to public transport facilities within 500 m from their place of living. There is a lot of variation in the availability of these facilities across different states and union territories. For instance, in Chandigarh, 100% of rural households have access to all-weather roads, and 99.5% have access to public transport within 500 m from their place of residence. On the other hand, in Meghalaya, only 64.7% of rural households have access to all-weather roads, and 82.6% have access to public transport facilities. States with higher levels of development and urbanization, such as Delhi, Goa, and Kerala, have higher percentages of rural households reporting the availability of these facilities. Surprisingly, some states with a lower level of urbanization, such as Manipur and Mizoram, also have high percentages of rural households reporting the availability of all-weather roads and public transport. In general, the data suggests that there is a significant disparity in the availability of facilities like all-weather roads and public transport across various parts of India, with some states and union territories having much better access than others.

Financial Institutions

Goa has the highest percentage of individuals with an account in both rural (97.9%) and urban (97.3%) areas. Nagaland has the lowest percentage of financial services in rural areas (66.5%), while Meghalaya has the lowest percentage in urban areas (79.5%). There are some States and Union Territories where the percentage of individuals with an account is higher in rural areas than in urban areas, such as Andhra Pradesh, Chhattisgarh, Himachal Pradesh, Jharkhand, Karnataka, Odisha, Rajasthan, Tripura, and Uttarakhand. On the other hand, there are some states and union territories where the percentage of individuals with an account is higher in urban areas than in rural areas, such as Assam, Gujarat, Telangana, and Uttar Pradesh. Overall, this table provides insights into access to financial services across different areas of India, highlighting the differences in account ownership between rural and urban areas and across different regions. Overall, the table highlights the disparities in access to mass media in different parts of India and can be a useful tool for policymakers and development practitioners to identify areas where interventions may be needed to improve access and reduce inequalities.

Coefficient of the Correlation Matrix of Indicators

The coefficient of correlation matrix has been analyzed to find out the relationship among various parameters of socio-economic development indicators in both rural and urban areas. It can be inferred from the coefficient correlation matrix in Figure 2 that access to piped water is positively correlated with access to improved sources of drinking water in both rural and urban areas, and the values lie at 0.88. It is very significant and highly correlated. It is natural that more access to pipe water will provide more sources of drinking water. Similarly, access to latrines is positively correlated with access to improved sources of drinking water; the value is 0.77, which highlights the importance of basic sanitation facilities for maintaining good health. However, access to a latrine is negatively correlated with all other indicators, which suggests that people who lack access to latrines tend to have worse socio-economic indicators overall. This highlights the importance of investing in basic sanitation facilities, particularly in rural areas where access may be limited. Access to clean fuel is positively correlated with access to improved sources of drinking water, which suggests that people who have access to clean fuel may also have access to other basic amenities. However, the correlation between clean fuel usage and other indicators is mixed, with positive correlations in some cases (e.g., access to improved sources of drinking water) and negative correlations in others (e.g., not in education, employment, or training).

The percentage of people who are not in education, employment, or training is negatively correlated with most indicators, particularly in rural areas. This indicates that people who are NEET tend to have worse socio-economic indicators overall and may require additional support to improve their standard of living. Access to facilities like roads and public transport is positively correlated with other socio-economic indicators in both rural and urban areas. Particularly, people who have access to transportation facilities may be more likely to have access to other amenities such as schools and markets (Table-2). The distribution of people with bank accounts is positively correlated with most other indicators in both rural and urban areas. This highlights the importance of financial inclusion in improving people's socio-economic status. Overall, this correlation matrix provides valuable insights into the relationship between various socio-economic indicators in both rural and urban areas. It may be useful for policymakers and development practitioners to identify areas for intervention and target resources towards improving access to basic amenities and promoting financial inclusion and education for all.

Table-2: Ranks of Selected Development Indicators for States/UT of India and Ranking Co-efficient according to Kendell's Method

State/UT	Access to piped water	Access to improved source of drinking water	Access to latrine	Clean fuel as primary source of cooking, heating and lighting	NEET	Percentage of rural households reporting availability of all-weather roads within 2 km from the place of living	Public transport facility within 500 m from place of living	Bank account	Access to mass media	Ranking Coefficient (Composite score)	Level of Development
	R1	R2	R3	R4	R5	R6	R7	R8	R9

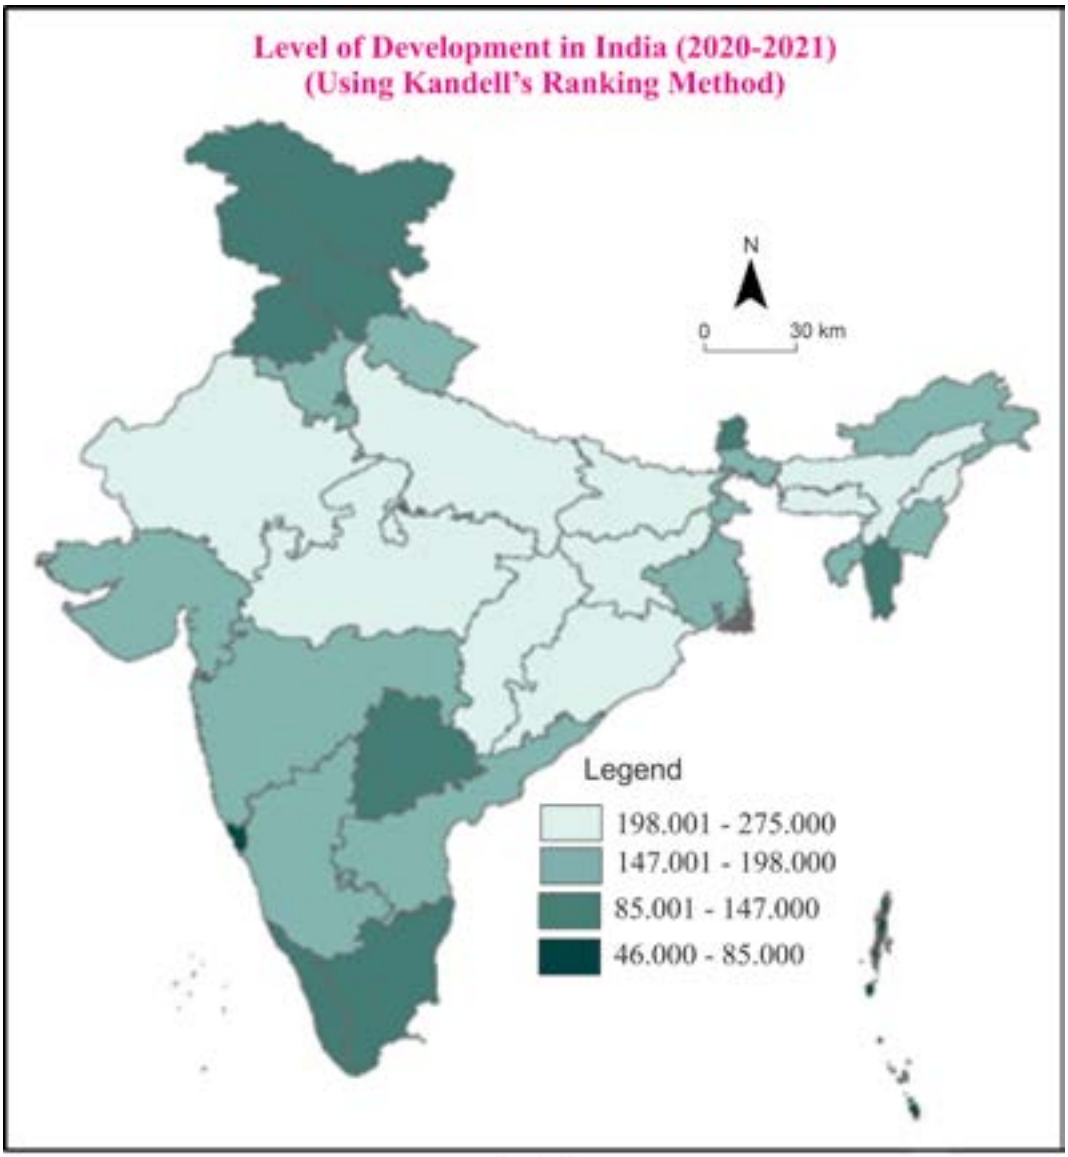
Level of Development

It is one of the simplest and quickest methods of computing composite score involving multivariate data with different units of measurement. Kendall (1939) used this technique for finding out agricultural efficiency in England and Wales using productivity data of different crops. The composite score, called ranking coefficient, in this case is found out for each spatial unit by simply adding the corresponding rank values of all the indicators. Table-2 provides information on various development indicators for different States and Union Territories (UTs) in India. These indicators include Access to Piped Water, Access to Improved



Level of Development in India (2020-2021)
(Using Kandell's Ranking Method)

Legend
198.001 - 275.000
147.001 - 198.000
85.001 - 147.000
46.000 - 85.000

Fig. 2

Source of Drinking Water, Access to Latrine, Clean Fuel as Primary Source of Cooking, Heating and Lighting, NEET, Percentage of Rural Households Reporting Availability of All-Weather Roads within 2 km from the place of living, Public Transport Facility within 500 m from Place of Living, Bank Account Access, and Access to Mass Media. In Andhra Pradesh, the state ranks 23rd in terms of access to piped water, while it ranks 19th in terms of access to improved source of drinking water. In addition, it ranks 8th in terms of having access to a public transport facility within 500 m from the place of living and 18th in terms of having access to a bank account.

The best ranking for any development indicator is found in Chandigarh, which ranks 1st in access to piped water, improved source of drinking water, latrine, and bank account access. The worst ranking for any development indicator is found in Arunachal Pradesh, which ranks 36th in access to clean fuel as a primary source of cooking, heating, and lighting and in Nagaland, which ranks 36th in access to latrine. Now, the Composite Score Value is calculated for each State/UT by adding up their rank values for each of the indicators. The State/UT with the highest composite score value is considered to be the least developed, while the State/UT with the lowest composite score value is considered to be the most developed. For example, the State/UT with the highest composite score value is Meghalaya with a score of 260, indicating that it is the least developed in terms of the indicators we have considered. On the other hand, Chandigarh has the lowest composite score value of 46, indicating that it is the most developed. Other states/UTs can also be ranked based on their composite score value; for instance, Jharkhand has a score of 275, which is the second highest, followed by Nagaland with a score of 235, and Chhattisgarh with a score of 236. Table-2 also showing the level of development of various States/UTs in India based on their composite score.

The States/UTs are categorized into four categories i.e highly, medium, least and low level of development (Fig. 2). The States/UTs with the highest composite score are Jharkhand, Meghalaya, Nagaland, Chhattisgarh, Bihar, and Odisha and are categorized as Least Developed. On the other hand, the States/UTs with the lowest composite score are Chandigarh, Puducherry, A&N Islands, Delhi, Ladakh, Goa, Lakshadweep, and Punjab and are categorized as Highly Developed. The other States/UTs with composite scores between the highest and lowest are categorized as Low and Medium Developed. The table gives an overview of the current state of development in different areas of the country and provides useful information for policymakers to identify areas for further development.

Conclusion

Based on the data presented in the tables, maps, and figures, it is evident that there are significant regional disparities in India, particularly in terms of access to basic necessities such as water, sanitation, education, and financial services. Rural areas tend to lag behind urban areas in terms of access to these necessities, with lower percentages of rural households having access to piped water, all-weather roads, public transport, bank accounts, and mass media. Similarly, rural areas have higher percentages of people not in education, employment, or training (NEET) compared to urban areas. These disparities are particularly pronounced in states such as Assam, Bihar, Jharkhand, Odisha, and Uttar Pradesh, which report lower levels of access to basic necessities across various indicators. It is therefore imperative for policymakers to prioritize and invest in improving access to basic necessities in rural areas, especially in states with high levels of regional disparities. This may involve providing infrastructure such as all-weather roads and public transport, promoting education and employment opportunities, improving access to financial services, and ensuring access to clean water and sanitation. Addressing these regional disparities can contribute to inclusive and sustainable development in India. In addition to regional disparities, the data in the tables also highlights other important issues. For example, the low percentage of households using clean fuel as a primary source of energy for cooking, lighting, and heating is a cause for concern, as this can have negative impacts on air quality and health. Similarly, the percentage of households reporting access to latrines by the majority of household members is relatively low in some states, highlighting the need for greater investment in sanitation facilities. Overall, the tables provide a useful overview of the various challenges and opportunities facing India. Addressing regional disparities and promoting greater access to basic necessities and financial services can contribute to inclusive and sustainable growth, improve the quality of life, and promote greater social and economic inclusion for all citizens.

A GEOGRAPHICAL ANALYSIS OF TRIBAL EDUCATION IN JHARKHAND

Alka Rani, Dr. Satya Prakash and Dr. Sanjay Kumar

Abstract

Although the rate of literacy among the tribal population is only 59.1% in India, it is lower than the national average of 74.4% (Census 2011). Education is one of the main forces behind a society's transformation. The literacy rate of Jharkhand's tribal population (57.1%) is still lower than the country as a whole, which is 59 percent (Census 2011) of India's tribal population. Upon reviewing a variety of literature, it has been found that factors such as cultural customs, poverty, the absence of educational institutions in rural areas, the medium of instructions, parental education, and school location all significantly contribute to the low enrolments of tribal students. According to the 2011 Census, in Jharkhand, 20.4% of the tribal population 46.4% of male and 53.6% of Female (6-15 age group) had never attended an educational institution. The objective of the study is to address the factors preventing tribal children from access to education and also to know the percentage who never attended educational institutions in Jharkhand. Coefficient correlation method is used to analysis the factors which is affecting the educational attainment of a tribal children. The present paper is mostly based on secondary data from various research studies including census data, Annual reports of tribal welfare ministry, Districts report card 2011, Jharkhand economic survey 2021, UDISE-2011.

Introduction

Education for the tribal population in India has been challenged due to historical marginalization and geographical isolation. (Brahmanandam T & Bosu T.2016:70). Education plays a significant role in overall development of an individual in a holistic way. Tribal people often called as Adivasi, Aboriginal, Indigenous people, first nation, Hunter-gatherers are the original inhabitants of a particular region or a country. (Michael A. Peters & Carl T. Mika 2017:1). The term ‘Adivasi', is used in the Indian context which is refer to as the tribal community (Xaxa, V. 1999:1).

There is significant percentage of tribal population in India, which contribute about 8.6 per cent population. Tribal population's literacy rate (58.96%) which is 14% lower than the national average (72.99%). The female literacy rate of India is 64.6% while the ST female literacy rate is only 46.4% (Census 2011). But however tribal population's literacy rate increased significantly from 8.53 percent in 1961 to 58.96 percent in 2011. In India, the total dropout ratio (DoR) of the tribal population of India (class I-VIII) stood at 69 % in 2001, but it subsequently decreased to 55% in 2011. (Educational Statistics at A Glance, 2012). The most common causes of school dropouts among tribal children in primary school are identified as household work, lack of parental guidance in studies, family socioeconomic status, school discipline (Soren, D. 2010:1). In term of education, health and economy concern tribal communities are still deprived as compared to general population. (Z. A. Bhat and M. A. Khan 2021 :659). More than 20–30% of India's tribal population, aged 6 to 15, has never attended school in the states of Madhya Pradesh, Himachal Pradesh, Bihar, Jharkhand, Odisha, Rajasthan, Uttar Pradesh. (census of India 2011). In the year, 2007-08, Five states namely Rajasthan, Jharkhand, Odisha, Chhattisgarh, and Madhya Pradesh together accounted 48 percent of STs in India but together accounted for 55 per cent of illiterate among STs (India human development report 2011:184). In Jharkhand, 20.4 per cent of the tribal population (age group 6-15) has never attended school in which 46.4 per cent are male and 53.6 per cent are female. Factors such as household income, caste, location, gender, and the level of education of the head of the household can significantly influence a parent's decision to send their child to preschool (Choudhury, P.K., Joshi, R. & Kumar,2021: 21). Tribal representation is very low in the nation's human development index and high in the human poverty index when compared to other social groups. (Patil, R. R. 2020:1).

To ensure the overall development and integration of tribal population into the mainstream of the society, it is necessary to educate them which directly contribute economic upliftment, empowerment, cultural preservation, social inclusion, health and hygiene, awareness of right, and gender empowerment. Literacy is one of the basic parameters for the overall development which encompass societal progress, economic growth and the overall wellbeing of communities. But in Jharkhand, Education sectors depicts a very poor situation particularly in term of enrolment and dropout of tribal students. The GER for school education in Jharkhand for ST was 106 percent in primary level which decreases to 87 percent in upper primary and 38 percent higher level of education. (Jharkhand economic survey 2021). We can see the trend of declining of enrolment ratio of ST students as when they grow in the higher level of education.

Study Region

Jharkhand is a state is eastern India lies on the Chhota Nagpur plateau, part of a vast deccan plateau that occupies most of the peninsular India. Major rivers like Koel, Damodar, Brahmani, Kharkai, Subarnarekha etc. flow over it. The average elevation of the area is approximately 1000ft. The state has total five divisions, (North Chhota Nagpur, South Chhota Nagpur, Santhal Pargana, Kolhan and Palamu) and 24 districts with total population of 32,988,134 total tribal population of 86,45,402 (26.2%). (census 2011). The total ST population is highest in the district like Ranchi 10,42,016 (12.05%) followed by Paschimi Singhbhum 10,11,296 (11.70%) Gumla 7,06,754 (8.18%) and then Purbi Singhbhum 6,53,923 (7.56%).The tribal communities like Santhal, Oraon, Munda, Kharia and Ho constitute the majority of the total tribal population and they speak Austroasiatic and Dravidian language. District wise distribution of tribal population shows that Khunti district has the highest percentage tribal population (73.3%), followed by Simdega (70.8%), Gumla (68.9%), Paschimi Singhbhum (67.9%).

Objectives

(1) To determine the percentage of tribal children (age group 6-15) who have never attended educational institution in the states of India and the districts of Jharkhand.
(2) To identify the factors preventing tribal children from having access to an education.

Database and Methodology

The paper used Census of India 2011 C-series data for the analysis of educational status of ST population in India with special focus on Jharkhand state. Beside these several reports and Jharkhand state database like Unified Districts Information for Education System 2011, Educational statistics at glance, 2012, National Sample Survey Organization 2010. Jharkhand economic survey 2021-22, District report card 2011, Tribal committee report 2014, Statistical profile of scheduled tribes 2013, Ministry of tribal affairs Annual report 2021-22, District elementary education report card 2011-12 (UDIES 2011) data have been used for analysis purpose. Pearson's correlation coefficient is most efficient common method to use for statistical technique for examining the linear relationship between the variables.

Result and Discussion

The Tribal population for the age group (6-15) who has never attended an educational institution is given in the table 1. More than 20% of the tribal population in states like Rajasthan, Madhya Pradesh, Odisha, and Jharkhand, Bihar, Uttar Pradesh has never attended an educational institution. An analysis of data by gender reveals that the proportion of female than male has never attended school. The primary reason for never attending an educational institution is indicated by the cost of school fees, and a lack of interest in learning, school far away, education not necessary are some reasons behind not enrolling themselves in the school. (National family health survey, 1998-99). The factors such as household income, caste, location, gender, and the level of education of the head of the household can significantly influence a parent's decision to send their child to preschool (Choudhury, P.K., Joshi, R. & Kumar, 2021:21). There is a severe teacher shortage in areas where tribal people predominate, affecting both tribal and non-tribal schools (Choudhary. K 2018:6). Less than 10% of the population in states and union territories like Himachal Pradesh, Uttarakhand, Sikkim, Mizoram, Kerala, Lakshadweep, Goa, Daman and Diu has never attended school. These states and territories show a positive picture of school enrolment.

Thus, the enrolment of tribal population in these states is good as compared to other states. Numerous initiatives, such as the introduction of midday meals, the opening of alternative schools, encouraging the involvement of Parent Teacher Associations (PTAs), and large-scale enrolment drives, have all contributed to the rising enrolment rate (Singh, P. 2017:817). An important feature of schooling in India is that despite of high enrolment rate, attendance is much lower than enrolment, and the difference between the two increased at higher level of education. (India human development report 2011: 180). The tribes' emphasis on educating boys, interpersonal issues like child marriage, a lack of family support, pressure from peers, and a personal lack of value for education have all contributed significantly to the high school dropout rate among tribal girls (Sucharita, V. 2023). The students of India do not attend elementary school for a variety of reasons, including poverty, lack of funds, discriminatory mindset, lack of planning, and ignorance on the part of their parents (Table-1). The educational background and family background of parents significantly impact their children's performance (Li, Z., Qiu, Z. 2018:3). It is important to note that both Punjab and Haryana have a predominantly non-tribal population compared to some other states in India so there is no data been found regarding these states. The north eastern states like Nagaland, Manipur, Mizoram,

Tripura and Meghalaya showing good enrolment of children (age 6-15) whose population of school attending is above 80 percent. In comparison to other regions of India, the tribal population in the northeastern state is more literate, and these regions are also more urbanized. Among the states with the highest ST literacy rates Mizoram, Meghalaya, Nagaland, Sikkim, and Manipur rank first, second, fourth, sixth, and eighth, respectively. (NSSO, 2010). Ministry of tribal affairs, Government of India has introduced special educational schemes and residential facilities such as Ashram school, Eklavya mode, Kasturba Gandhi Balika Vidyalaya, Jawahar Navodaya Vidyalaya and various vocational training centers were open in the tribal areas.

Table-1: Scheduled Tribes and Educational Institutions in 2011

These initiatives make easier for the tribal children to access to schools. One fifth of the children in the age group of 6-15 years were out of the school and financial constraint was an important reason for discontinuation of education. (India human development report, 2011:180). In order to provide the children with a high-quality pre-school education, the Anganwadi are inadequately trained in early childhood development techniques. As a result, most children are insufficiently ready to start school and pursue their education. As a result, learning standards are still low and dropout rates in the early grades of primary school remain extremely high. (India human development report 2011: Planning commission 2014:194). (Table-2)

Table-2 displays the proportion of the population in the district of Jharkhand that attends or has never attended an educational institution. The proportion of scheduled tribes who has never attended educational institution is higher than that of non-tribal population in Jharkhand. The districts like Koderma (41.9 %), Godda (30.5%), Sahibganj (30.1%), Pakur (31.5%) and Paschimi Singhbhum (28.8%) have higher percent of tribal population who has never enrolled in any educational institutions (6-15 age group). (Fig. 1) Less than 20% of the tribal population in districts like Ranchi, Ramgarh, Simdega, Lohardaga, Khunti,

Source: Census of India, 2011

and Purbi Singhbhum has never attended school and rest of the districts lies in between 20- 30 percent of tribal population who never enrolled in school. We can see the regional wise differences in the districts of Jharkhand who has been attended the school. The students' learning process was complicated by the teacher's unfamiliarity with the tribal dialect. A few of the difficulties faced by first-generation learners include fear of teachers, difficulty understanding subjects like Mathematics, Hindi, and English, and a nonfunctional parent teacher association that hampered learning and increased dropout rates (Ottaplackal, J. J., & Anbu, K. 2022:26). Appropriate early childhood education in tribal communities will undoubtedly contribute to fostering a love of learning at an early age and lowering the school dropout rate (Asha, C. M. 2020:1396). Most of the tribes live in steep terrain, forested areas, and remote areas. The tribal children live in remote areas, which makes it difficult for them to receive an education (Majumder, A. 2018:102). Additionally, among the social groups, the majority of SC/ST children attend government schools, which lowers the number of children who do not attend school. Girls outnumbered boys in the group of kids who were not attending school because "education was not considered necessary (Sankar, D. 2008:5). Positive attitude towards education and tribes living standard are strongly corelated, that is families with stronger economic background tend to have a higher proportion of literate member to families with weaker backgrounds. (Gupta, S., & Nanda, P. 2008:65). Tribal girls are prevented from attending and remaining in school by widespread gender-specific discrimination and stereotyping in Indian society (Sucharita, V. 2023:11). The majority of schools in tribal areas lack even the most basic facilities. Tribal areas typically have poorly maintained school buildings. Many tribal schools lack even blackboards and proper teaching and learning procedures (Jai Prabhakar, S. C. 2018:73).

After analyzing Pearson coefficient correlation by using data from the Census of India 2011, and UDIES 2011, Here several variables have taken like literacy of a family, socio-economic condition of a family, poverty, level of urbanization are the factors which effect the educational attainment of a children. we conclude that a family's socioeconomic status and level of education of parents effect the educational attainment of children. The correlation coefficient (r) value of tribal population never attended (6-15 age) and household using river as a source of drinking water is .499 which shows moderate positive association between both the variables. The P value is <0.05 (0.013) which means the relationship is statistically significant. So, we can say that increases in the dependence on river water also increases the population of never attended educational institutions.

Similarly, household using firewood and cow dung as a source of cooking showing (r) value of .415 showing moderate positive and P value is <0.05 (.044) which shows a significant relation. When we taking Electricity as a source of lighting in a household, it showing a negative relation with population never attended educational institution. The P value of <0.05 (.011) showing a significant relation. Lighting with electricity reduces the number of never-attended educational institutions. The social and economic aspects of any community have a big impact on education. (Lagravinese, Liberati, & Resce, 2019:18). Appendix 3 shows the strong negative relation of literacy with population never attended educational institutions. The (r) value of literacy is (-.850) with p value of <0.01 (0.000) showing a significant relation. It is evident that high literacy rates are correlated with high school enrolment rates and the population having low level of education are associated with a high proportion of the population that has never attended an educational institution. When compared to ST female literacy, there is also a clear negative correlation with the population that has never attended school with (r) value of -.584 and P value <0.01 (0.003) significant at 0.01 level. Poverty is again a significant factor in affecting education of a child. The correlation matrix shows a moderate positive correlation of poverty with (r) value of .405 with person never attended educational institutions. It is significant at 0.05 level with P value of 0.050. The percentage of population who have never attended an educational institution rises along with the level of poverty. Higher the level of poverty also increases the number of children who has never attended the educational institutions. Taking urbanization into consideration, which is strongly negative corelated with population never attended educational institutions with (r) value of -4.30 which is significant at 0.05 level with p value of 0.036. It demonstrates that the proportion of tribal people who have never attended an educational institution is lower in urbanized areas. The One of the most economically disadvantaged and marginalized groups in India is represented by the ST (Sahu 2014:1). The It is likely that the socioeconomic status of the family influences the decisions made by parents regarding whether or not to send their children to preschool (Ghosh, S. 2019:148).

Conclusion

This paper shows a descriptive analysis of the Indian states and the districts of Jharkhand that have never attended educational institutions of age group (6-15). Although the literacy rate among tribal population is increasing, it is doing so at a slower pace than it is among non-tribal people. According to census 2011, 18% of

the tribal population in India, comprising 46.4 % of male and 53.2 % of female, are not enrolled in school. In Jharkhand, 20.4 percent of tribal population (6-15 age group) 46.4% of male and 53.6 % of female have never attended school. The data indicates a percentage of females are high as compared to male counterpart who have never been sent to school. More than 20% of the tribal population (6-15 age group) in the states like Rajasthan, Rajasthan, Madhya Pradesh, Bihar, Uttar Pradesh, and Jharkhand, have not enrolled in the schools. However, in the southern Indian states, like Kerala, Karnataka, Andhra pradesh, Tamil Nadu the percentage of never enrolled tribal students is low as compared to north Indian states. The ignorance and neglect of parents regarding their children's education is a serious problem as well. Poverty is a major barrier to educational access because it keeps underprivileged households from funding their children's education with money for supplies like books, school supplies, uniforms, meals, and transportation. Another challenge in providing elementary education to tribes is their geographic location. Undoubtedly, a number of factors can have a significant impact on the educational attainment of children of Scheduled Tribes (ST) in Jharkhand and many other regions. These factors include poverty, socioeconomic status, literacy, and school facilities. Consequently, Tribal education is very important because it is essential to the growth and well-being of indigenous communities worldwide and also tribal education must be taken into consideration as a way to support the population's growth and integration into society at large.

POPULATION DENSITY AND URBANIZATION EFFECTS ON AGRICULTURAL LANDUSE IN LUCKNOW DISTRICT

Vivek Kumar and Dr. S.P. Asthana

Abstract

This research paper is a comprehensive exploration of the intricate interplay between population density, urbanization trends, and their profound repercussions on agricultural land use patterns within Lucknow District, Uttar Pradesh. Against the backdrop of Lucknow's rich historical, cultural, and economic heritage, the study investigates the transformative impacts of rapid urbanization on the allocation and utilization of agricultural land. The findings, spanning the decade from 2001 to 2011, reveal notable changes in various land use categories, including a substantial decrease in forest land, cultivable wasteland, and current fallows. The increase in areas other than agricultural land use underscores diverse transformations beyond traditional agricultural activities. The research emphasizes the need for sustainable land management practices, considering the challenges posed by urban expansion to traditional farming practices. The conclusions drawn from this study provide valuable insights for policymakers, land managers, and urban planners, offering a nuanced understanding of the challenges and opportunities at the intersection of urban development and agriculture. The research aspires to contribute to the academic discourse on evolving land use dynamics, offering practical implications for sustainable land management and informed decision-making processes, specifically tailored to the unique context of Lucknow District.

Introduction

The research endeavours to conduct a comprehensive examination of the intricate interrelationships among population density, urbanization trends, and their profound impacts on agricultural land use patterns within Lucknow District, Uttar Pradesh. As urbanization undergoes unprecedented growth, it exerts significant pressure on the allocation and utilization of agricultural land, posing challenges to traditional farming practices. Lucknow District, with its rich historical, cultural, and economic heritage, provides a compelling backdrop for this study.

The rapid urbanization witnessed in recent years has transformed the landscape, necessitating a closer examination of how these changes influence the agricultural sector. The research aims to unravel the nuanced dynamics of this interaction, exploring how increasing population density and urban expansion reshape the agricultural land use mosaic. Through a meticulous geographical analysis, the study seeks to identify the specific effects of urbanization on the distribution, quality, and productivity of agricultural lands in the district. This investigation becomes particularly crucial given Lucknow's significance as a major urban center within the state of Uttar Pradesh. The findings of this research are anticipated to provide valuable insights for policymakers, land managers, and urban planners, fostering a deeper understanding of the challenges and opportunities that arise at the intersection of urban development and agricultural sustainability. In essence, the study aspires to contribute to the academic discourse on the evolving dynamics of land use in the face of urbanization, offering practical implications for sustainable land management and informed decision-making processes tailored to the unique context of Lucknow District.

Study Region

Lucknow district is a district located in the state of Uttar Pradesh in northern India. The city of Lucknow is the district headquarters and the district is part of Lucknow Division. It also is the capital of Uttar Pradesh. Lucknow is Bounded on the east by Barabanki district, on the west by Unnao and Hardoi districts, on the south by Raebareli district and in the north by Sitapur district. It is geographically located between latitude 26° 30' North and longitude 80° 30' East. Lucknow district covers an area of 2,528 square kilometers, centrally located in both the central Ganges plain as well as Uttar Pradesh as a whole. The climate of Lucknow district is predominantly subtropical in nature, and it experiences the effects of the South Asian monsoon. Lucknow district is divided into 4 tehsils: Lucknow, Malihabad, Mohanlalganj, and Bakshi Ka Talab. These tehsils are then divided into 8 community development blocks. According to the 2011 census Lucknow district has a population of 4,589,838. This gives it a ranking of 31st in India (out of a total of 640). The district has a population density of 1,815 inhabitants per square kilometre (4,700/sq. mi). Its population growth rate over the decade 2001-2011 was 25.79%. Lucknow has a sex ratio of 906 females for every 1000 males, and a literacy rate of 79.33%. 66.21% of the population lived in urban areas. According to the 2001 census Lucknow district had a population of 3,681,461.

Objectives

(1) Examine the specific effects of urbanization on agricultural land use, including changes in landscape, land conversion, and potential loss of arable land.
(2) Analyze the dynamics of land conversion and its consequences for the overall agricultural landscape.
(3) Identify challenges and opportunities arising from the interplay between population density, urbanization, and agricultural land use.
(4) Highlight the need for sustainable land use practices in the face of a growing population in Lucknow District.

Database and Methodology

This research paper is based solely on secondary data. The approach involves a systematic and structured process for collecting, analyzing, and interpreting existing information. Secondary data from reliable sources such as government reports, statistical databases, academic journals, and research publications has been used for collection of data. Demographic data, urbanization statistics, and agricultural land use information has been collected. A comparative analysis of urban and rural areas within Lucknow District to discern differences in agricultural land use patterns has been done. By relying on secondary data, this research methodology aims to provide a comprehensive understanding of the complex relationships between population density, urbanization, and agricultural land use in Lucknow District.

Result and Discussion

Urbanization and Population Density in Lucknow District

In 2001 Lucknow District had a total population of 3,681,461, the population density was 1453 persons / sq. km. The urbanized population was 63.3%. In 2011, the total population of Lucknow District increased to 4,589,838 and the population density increased to 1815 persons / sq. km. The urbanization was 66.21%. The decadal population growth rate between 2001 to 2011 was 25.79%. (Fig. 1) The uptick in urbanization from 63.3% to 66.21% underscores the transformative impact of urban expansion on the district's landscape. This demographic shift is crucial in the context of the research paper, as heightened urbanization tends to exert substantial pressure on agricultural land. As the population grows and urban areas expand, agricultural land faces challenges such as conversion, potential loss of arable land, and changes in land use patterns (Table-1, 2 and 3).

Source: Calculated by Authors Note: Area is in hectares

TRA

The total agricultural land in Lucknow District showed a marginal decrease from 251,853 hectares in 2001 to 251,596 hectares in 2011, reflecting a slight decline of 0.10% over the decade.

Forest

Forests in cities play a crucial role in enhancing air quality by absorbing pollutants, providing essential green spaces for recreation and mental well-being, and contributing to overall biodiversity (Fig. 1). They act as urban lungs, mitigating the impact of pollution and fostering a healthier, more sustainable urban environment. Additionally, urban forests contribute to temperature regulation and act as a natural habitat for diverse flora and fauna, promoting ecological balance within cityscapes. Forest land witnessed a substantial reduction from 20,967 hectares in 2001 to

12,000 hectares in 2011, indicating a significant decrease of 42.76%. This decline suggests potential urbanization effects, changes in land management, or alterations in forest policies.

Net Sown Area

Net sown area refers to the total cultivated land excluding fallow land. It represents the portion of agricultural land actively used for sowing crops during a specific agricultural season. Calculated by deducting the fallow land from the total cultivated area, net sown area provides insights into the actual land under cultivation, essential for assessing agricultural productivity and planning resource allocation. Net sown area in the study area slightly decreased from 139,772 hectares in 2001 to 135,737 hectares in 2011, reflecting a decline of 2.88%. Possible influences include changes in agricultural practices, land use priorities, or urbanization effects.

Cultivable Wasteland

Cultivable wasteland refers to land with potential for cultivation that is currently unused or underutilized. It encompasses areas suitable for agriculture but left fallow or abandoned. Rehabilitating cultivable wasteland can significantly contribute to expanding agricultural productivity and addressing food security concerns by bringing additional arable land into cultivation. Cultivable wasteland in Lucknow experienced a notable decrease from 7,734 hectares in 2001 to 5,501 hectares in 2011, indicating a substantial decline of 28.87%. Possible causes include changes in agricultural methods, land reclamation, or urban development.

Current Fallows

Current fallows refer to agricultural land left uncultivated for one or more regular crop-growing seasons. These fallow periods are intentional and part of the crop rotation system to allow the land to regenerate fertility. By allowing fields to remain fallow temporarily, farmers can manage soil health, prevent depletion, and enhance overall agricultural sustainability. Current fallows decreased significantly from 26,737 hectares in 2001 to 16,224 hectares in 2011, reflecting a substantial decline of 39.32%. This suggests changes in agricultural practices, land utilization patterns, or increased cultivation efficiency.

Fallows Other Than Current Fallows

Other fallows, apart from current fallows, include: Fallow land left uncultivated for an extended period beyond the regular crop cycle, known as "fallow land other than current fallow, temporary fallows where land is intentionally left unused

for a shorter duration to manage crop rotation effectively and in some cases, fallow lands are left to regenerate naturally, aiding soil recovery and preventing degradation for improved long-term agricultural productivity. The category of fallows other than current fallows increased moderately from 14,164 hectares in 2001 to 15,358 hectares in 2011, in the study area, indicating growth of 8.4%. Possible interpretations include changes in fallow land management strategies or shifts in agricultural planning.

Barren Land

Barren land refers to areas that are unproductive and unsuitable for cultivation due to factors like extreme aridity, poor soil quality, or environmental degradation. These lands lack the necessary conditions to support plant growth and agricultural activities. Barren lands contribute to challenges such as desertification and are often targeted for conservation or reclamation efforts to mitigate environmental impacts. In the District, Barren land decreased from 8,963 hectares in 2001 to 6,775 hectares in 2011, indicating a decline of 24.41%. Potential factors contributing to this decrease include urbanization, land reclamation, or improved land management practices.

Other Than Agricultural Landuse

Other than agricultural land use in cities includes various categories such as residential, commercial, industrial, and institutional land uses. Residential areas cater to housing, while commercial zones are designated for businesses and trade. Industrial zones accommodate manufacturing activities, and institutional areas include spaces for schools, hospitals, and other public facilities, collectively contributing to the diverse urban landscape and functionality. Other than agricultural landuse saw a substantial increase from 27,278 hectares in 2001 to 55,014 hectares in 2011, indicating significant growth of 101.67%. This emphasizes the need for understanding diverse transformations, potentially beyond traditional agricultural activities.

Pasture Land

Pasture land is open land used for grazing livestock, providing a natural environment for animals to feed on grass and other vegetation. These areas support the husbandry of livestock like cattle, sheep, or goats, promoting sustainable agriculture and animal husbandry practices. Pasture lands play a crucial role in maintaining ecological balance, preventing soil erosion, and supporting the livelihoods of pastoral communities. Pasture land decreased slightly from 3,104 hectares in 2001 to 3,051 hectares in 2011, reflecting a decline of 1.70%.

Possible causes include changes in livestock management practices or alterations in land use priorities.

Area of Garden, Trees and Shrubs

The area of garden, trees, and shrubs refers to the collective space dedicated to cultivated ornamental plants, trees, and bushes. This encompasses landscaped areas within residential, commercial, or public spaces, contributing to aesthetic beauty, environmental benefits, and recreational value. The careful planning and maintenance of these green spaces enhance urban aesthetics, air quality, and overall well-being. The area of garden, trees & shrubs notably decreased from 3,132 hectares in 2001 to 1,936 hectares in 2011, indicating a substantial decline of 38.22%. Implications may include changes in landscaping preferences, urban development, or altered land use priorities.

Conclusion

This research paper has provided a comprehensive examination of the intricate interrelationships among population density, urbanization trends, and their profound impacts on agricultural land use patterns within Lucknow District, Uttar Pradesh. The study elucidates the evolving dynamics of land use in the face of unprecedented urbanization, particularly focusing on the changes witnessed over the decade from 2001 to 2011. The findings reveal significant transformations in various land use categories, emphasizing the intricate balance between urban expansion and agricultural sustainability. Notable trends include the decrease in forest land by 42.76%, reflecting potential impacts of urbanization and changes in forest policies. Additionally, the decline in cultivable wasteland by 28.87% suggests alterations in agricultural practices or land reclamation efforts. The substantial decrease in current fallows by 39.32% indicates shifts in agricultural practices and increased cultivation efficiency. Importantly, the considerable increase in areas other than agricultural land use by 101.67% underscores the diverse transformations occurring beyond traditional agricultural activities. The findings highlight the need for sustainable land management practices and informed decision-making processes tailored to the unique context of Lucknow District. As urbanization exerts pressure on agricultural land, the study emphasizes the importance of striking a balance to ensure the coexistence of urban development and agricultural sustainability. The research contributes valuable insights for policymakers, land managers, and urban planners, fostering a deeper understanding of the challenges and opportunities at the intersection of urban development and agriculture.

In essence, this research aspires to contribute to the academic discourse on the evolving dynamics of land use, offering practical implications for sustainable land management and decision-making processes in the context of rapid urbanization. The insights gained from this study can inform future policies and initiatives aimed at ensuring a harmonious coexistence between urban development and agricultural resilience in Lucknow District and similar regions facing similar challenges worldwide.

Abstract

Land is a basic natural resource. It forms the basis for all the biological, human and economic activities. In the developing countries like India, where agriculture is the main source of economy and livelihood for more than two-thirds of the working population, proper utilisation of land resource is vital.

Introduction

In recent years, serious concern has been shown on ecological management and optimum utilization of land resources for the benefit of mankind. Hence the use of land resource is "central to all discussions of land problems and policies [(1)] . Land use at any region is a complex, diversified and dynamic concept. It is due to the operation of whole range of environmental factors but modified by socio-economic and historical elements. In dry areas, the use of land resources is virtually associated with climatic and edaphic conditions, besides the socio-economic needs of the mankind. Undoubtedly, the erratic behaviour of the monsoon, frequent occurrences of drought and prolonged dry spells have had a devastating and debilitating effect on land use pattern and as a result, the landscapes in dry areas gets continuously varied and modified. Since land itself is one of the important components of the ecosystems, a critical study on landscape ecology and its planning calls for greater attention to be paid to the drought prone areas to keep the ecological balance between the environment and the socio-economic needs of the region.

Ecological View of Landscape

In the sense of ecology, land carries ecosystems, but is itself also a part of these ecosystems. Although the use of land resource may be considered from abroad view of human welfare, its use is always a process of modifications of ecosystem. The idea that land use is a process of modification of ecosystem was well explored by Simmons [(2)] .

He suggested that land use ecology might form a central theme in biogeography. It is also mentioned that the ecosystem concept provides the necessary modern scientific framework to the study of land use. The form and function of land use is a human enterprise, while the development of landscape is the continuous efforts of man for his needs and sustenance under every possible combinations of terrain, climatic, edaphic and vegetative conditions. By all means, it suggested that any scientific and rational land use planning should see that the ecological balance was not disturbed and that proper equilibrium between the environment and the socio-economic needs of the area be maintained.

Ecological Problems of Land Use

In the process of land use management and optimisation, ecological problems are becoming a most serious concern. The ever increasing pressure of population and decreasing man-land ratio are posing challenging problems to the land-use planners. Structurally, a land-use system consists of three interacting spheres namely, ecological (environmental), economic and social. Each sphere has its own unique set of human-ascribed goals. Ecological problems are those, which appear in connection with human socio-economic needs, change the quality of the physical environment and indiscriminate use of natural resource base. Ecological problems appear in different types of physical environment and various socio-economic, technological and political conditions.

The negative ecological effects like degree of decertification, land degradation, soil erosion, soil salinisation, chemical contamination and water pollution are frequent in the dry areas but taking place in different intensities and degree of criticality. The other problems related to land use are under-utilisation, over-utilisation and mis- utilisation of land resources. So the question is what are the reasons for the appearance of negative ecological effects in different environmental and socio- economic conditions. Off all, undoubtedly, man's indiscriminate use of land resources has resulted in the creation of negative ecological effects. His failure to recognise the long term implications of deforestation, faculty methods of cultivation, overgrazing, massive application of fertilisers and pesticides, practice of single crop monocultures, imbalances in the input and output factors and large scale exploitation of land and soil resources throughout an entire ecosystem. Results in widespread degradation.

The practice of monoculture was accompanied subsequently by great losses of genetic varieties in the fields, involving high risks of large hectarages being destroyed by single drought or pest. To cultivation of the same crop continuously and their synthetic fertilisation year after year has resulted in the disruption of the soil balance. With diminishing organic matter in the soil, its ability to retain moisture is also reduced and as a consequence, the soil becomes sterile and dry. To circumvent some of these problems a critical examination of landscape ecology is essential for a more rational approach to land use planning and conservation of resources.

Eco-development and Ecological Planning of Land Use

Generally speaking, ecological planning is a fundamental tool for landscape and regional planning, such that many landscape ecological studies are now done as integral parts of landscape and regional planning projects[3] . It offers an effective means of helping mankind to adapt to the dynamic changing environment of which he is but one integral part. Mc Harg[4] has defined ecological planning as "an instrument for revealing regions as interacting and dynamic natural systems having intrinsic opportunities and constraints for all human uses.

The goals of such planning are derived from the region and its people as proffered by locations where all or most advantageous (safe, healthy and beautiful) factors exist with none or few detrimental factors for any and all anticipated future uses. What constitutes 'detrimental' or 'advantageous' is derived from the use itself and the value system of the initiating person or group. The concept of eco-development forms the main strategy of 'Habitat Ecology'. It helps in explaining the form of planned growth which is concerned with the development of local available land resources within the constraints of local environment with a view to optimise the local capacities of the biosphere to support the welfare of life. The eco-development approach is very close to ecological and environmental planning to balance and harmonise the various enterprises of land use which man for his own benefit has superimposed on physical environment.

The eco-development approach related to land use rests on (i) rational utilisation, (ii) development of mankind pertaining to their well-being rather than in economic sense, and (iii) advancing a true symbiosis between man and environment. To activate and regulate the harmony between landuse development and environment both the demand and supply side of the equation must be acted upon. In the eco-development and ecological planning sense, any land use planning should not be considered merely from the agricultural point of view and bringing more land under the plough making it viable for cultivation, but should include rational utilisation of land resource, conservation of land from erosion, development of nutrients and soil cover through multiple vegetative systems, improving the potential capacity of land, application of modern scientific technology and lastly the preclusion of over exploitation of land.

Study Region

Anantapur district is one of the chronically drought-prone areas in the country. It is located in the rain-shadow region of

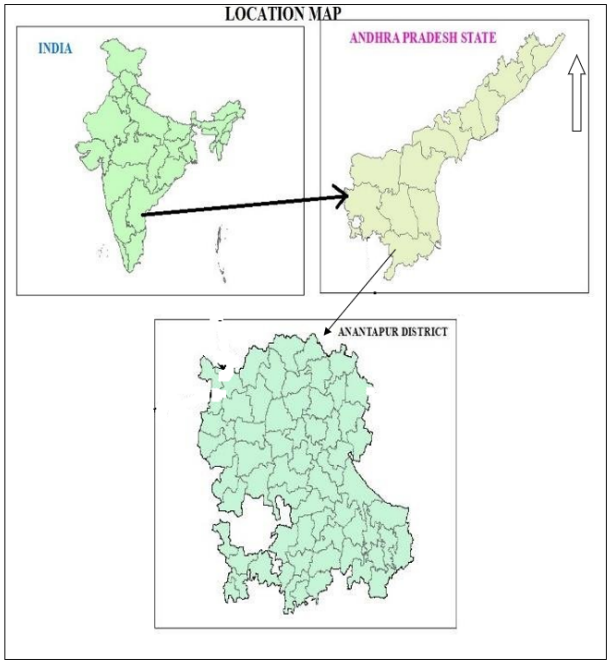

Fig. 1. Location map

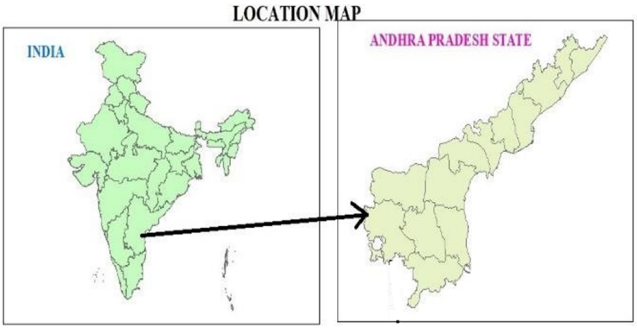

Fig. 2. Location map

the Western Ghats in Andhra Pradesh. It is the largest district in terms of area in the State. The population spread is very sparse with a density of population of 166 persons per Sq.Km. Agriculture is the predominant occupation of the people. The average annual rainfall of the district is 544 mm. with the lowest number of rainy days of 35 in the State. The district has been experiencing a drought once in every two years which is really serious and detrimental to stable agriculture.

Methodology

The spatial distributional pattern and changes in important land use types namely, forest land, fallow land and crop-land are examined and delineated with the help of both quantitative and cartographic techniques. The quantum of change is determined through percentages, regression trend and growth rates The impact of rainfall on land use types is measured with correlation testing.

Forest Land Use

Forests form distinct ecosystems. In fact, Anantapur district is very poor in forest cover with only 10.3% of the total geographical area of the district. The nature and character of forests in the district does not indicate any dense growth of tree population with different variety of plants. The forests of the district may be described as dry mixed deciduous and thorny open scrub types.

The distribution of forest-cover in the district is not only very low in proportion but also most uneven. Relatively, higher concentrations (15.1-20% and >20%) of forest-cover are found in southern, south-eastern and north-eastern parts of the district. In these areas, the amount of rainfall is comparatively higher than the other parts of the district. The western part of the district is found with very thin forest cover with discontinuous thorny thickets and scrub woodlands whose vegetative growth is stunted due to poor edaphic and very low isohyetal conditions.

During the three decades under consideration (1960-90) total area under forest has not shown any substantial change but showed a small increase of 0.1 per cent or 2000 hectares. The regression analysis has also revealed that the trend of forest land is marginally positive with 2 per cent of the goodness of fit. The annual compound growth rate has also shown a negligible rate of increase of 0.003 per cent.

Planning for the Development of Forest Land

In drought-prone areas, maintenance of ecological balance is one of the most important considerations to build-up the humus contents in the soil, avert soil erosion, increase the moisture in the atmosphere, raise the ground water level and heap in ground water recharge and storage besides other economic purposes. However, the poor quantity of forest cover in the district is too short to fulfil the requirement of ecological balance and is seriously jeopardizing the ecosystem of the region it is necessary to take up massive efforts on war-footing to develop forest-cover in the district

The development of forest-cover in the district heavily depends upon the (i) plantation of drought resistant species in large parts of the reserve forest areas, which are devoid of any vegetative cover, (ii) there are number of tanks in the district which are silted and do not fill up with meagre rainfall The foreshore of these tanks can be planted with eucalyptus and subabul plantations., (ii) depending upon the suitability of site and topography, particularly in the slopy agricultural lands and cultivable wastelands and all along the road sides the species like tamarind, neem, gulmohar, eucalyptus, fruit and flowering plants can be planted extensively. Agave species

can be planted in 'estate concept' mainly to yield raw material for fibre extraction and to put otherwise unproductive areas to productive use and (iv) pasture development can be taken up on the barren hills, slopy soils, community lands and village poramboke lands. Having all the afforestation schemes, it is utmost necessary to convert this dry belt gradually into a green belt for balancing the ecosystem.

Fallow Land Use

Land under fallows accounted for 17 per cent of the geographical area of the district. which is indeed a high proportion. More than one fifth of the geographical area under fallows is found in 17 mandals mostly located in western and north-eastern parts of the district.

During thirty years period, the proportion of fallow land has increased by 5.6 per cent amounting to about 106 thousand hectares. The increase is found in many parts of the district. The regression analysis has also confirmed this trend of increase of fallow land but is accounted by 22 per cent of co-efficient of determination. It indicates that the increase in the area under fallows is not perpetual from year to year but highly fluctuating. The annual average rate of increase is 0.6 per cent.

It is suggested that an increasing trend of fallow land should be controlled and utilised at optimum level through scientific land use management systems. If possible all the fallow lands should be brought under dry farming cultivation with suitable drought resistant rain-fed crops like millets, pulses, fodder crops and agro-forestry A considerable change in the outlook of farmers is to be brought out from traditional practices to new methods of dry farming for optimum use of fallow lands with multi-tier vegetations in different ecological systems and the sound management of Sylvi-Agri-Pastoral Systems.

Agricultural Land Use

The district has vast agricultural land resource base but suffers from instability due to vagaries of monsoon. The net area sown in the district accounted for 49.9 per cent of the total geographical area which is significantly. Higher than the average proportion of net sown area in Andhra Pradesh State (41.3 per cent)

The quantum of change in the proportion of net area sown during 1960- 1990 showed a significant decline of 5.5 per cent amounting to 105 thousand hectares. The trend of net area sown in the district has been negative. The goodness of fit of the regression trend states that the present negative trend is to the tune of 11 per cent only. It means that the negative trend of the net area sown is not exactly perfect but it is highly fluctuating from year to year depending on the variation of rainfall On an average, the annual compound growth rate declined at 0.03 per cent.

Impact of Rainfall on Arable Land

In the drought-prone region, where rain-fed farming is predominant and irrigation development is very low, it is a common assumption that the increase or decrease in either cropped area or fallow land will be in close association with the success or failure of monsoons. In the present study, the correlation analysis has revealed that there has been a positive correlation between rainfall and net area sown in the district to the tune of 0.55 Co-efficient value and negative correlation between rainfall and fallow land to the tune of 0.62 co-efficient value. A high negative correlation of 0.85 is found between net area sown and fallow land. It shows that if there is an increase in rainfall, the land under cropping may increase or if there is decrease in rainfall, the land under fallows may increase. It indicates that these two land use types are inversely correlated and functionally related with each other.

Strategy for the Development of Suitable Cropping Pattern

The present cropping pattern dominated by groundnut, cannot be treated as inappropriate and it appears to be a more or less natural consequence of the poor natural resource endowments of the district. Now that it required all the more is the optimisation and strengthening of present cropping pattern without further spatial extension of mon-crop groundnut. In view of varying drought conditions and agricultural drought which differs from one crop to another crop in an area, an extending monoculture groundnut farming to wider area may not be advisable, as a wide-spread drought may adversely affect the agricultural economy of the district. In such circumstances, all rainfed crops which are of high value and low water consuming must be preferred. The risks from droughts could be reduced by popularising suitable inter-cropping methods. If there is failure of rain, at least one of the component crops will yield something and thereby minimise the risk of total loss. The non-traditional crops like sunflower, safflower and castor etc. should also be grown in the suitable soil and moisture conditions.

Soil Characteristics and Problems

The soil is a dynamic layer which immediately reacts to the pattern of its use or changes in the soil forming environment. The district has 82 per cent of red soils and 18 per cent of black soils. The phosphorus and organic matter 3 content is poor in 82 to 90 per cent of the soils. But more than 90 per cent of the soils are moderately rich in potash more than 95 per cent of the soils are neutral or weakly alkaline. Less than 5 per cent of the soils are having severe saline and or alkaline problems.

The results of studies made by different organisations reveal that the soil characteristics are being changed in a short span of time by such activities of man like (i) removal of vegetation cover, (ii) application of heavy irrigation, (iii)

change of cropping pattern and (iv) change of morphology. The conclusions are that (1) in the undulating piedment regions where dry farming is practiced there is an increase of rill and gully erosion, (2) there is steady increase in the salinity and alkalinity problems in the canal irrigated mandals like Rayadurg, Gooty. Tadipatri and Anantapur, (3) there is a decreasing tendency in the potassium content of the soils particularly in the paddy cultivated areas and (4) with the shift from millet oriented to groundnut oriented cropping pattern, the soils have shown sulphur and zinc deficiency. Iron deficiency is also predicted in the near future.

Soil Management

The soil management programme in a semi-arid region like Anantapur district should be comprehensive and integrated one. First and foremost adequate importance should be given to the extension programmes to create the awareness in the farming community about the dangers of the mismanagement of the soil ecosystem and to motivate them to follow proper soil management 2 guidelines. The soil forming environment could be improved by managing catchments at t micro-level Construction of check dams and watersheds on small catchments serves as a multi-purpose schemes in this direction Both agronomic and engineering measures of soil conservation should be implemented in a complementary manner to achieve better results. The alkalinity and salinity problems of the soils have to be solved with suitable measures like zypsum application and leaching of excessive salts with suitable dosage of irrigation respectively Proper care should also be taken to minimise water sepage from the irrigation canals which will lead to the problems of salinity and alkalinity.

Conclusion

It has been observed that man, rather than the nature is bringing considerable change in the quality of land in a short span of time. The short- sighted and unplanned commercial and subsistence gathering of resources from the nature's bounty have caused considerable damage to the land system Many of his activities though fetching short-term gains, are causing long-term and sometimes irreversible damages to the quality of landscape system in this dry region. In view of very low proportion of forest cover, high proportion of fallow land, instability in agriculture land followed by mono-cultures and poor nature of soil cover, the landscape ecosystem of this region is delicate and is being easily disturbed.) The maintenance of ecological balance is one of the most important 4 considerations and is to be looked into it very seriously. To achieve the required goals, "Sustainable Land Use Development" is the way of environmental feature. Jacobs [5] has referred to sustainable development as "the offspring of ecological planning". To understand both and carry them out, environmental education is essential at all levels and in all sectors of the population.

It is also often emphasised that the transformation of rural habitat is the fundamental lead for the eco-development of the region the integrated Rural Development (IRD) is to be concerned with ecological and environmental issues in addition to the integration of sectors and policies in space-time dimensions. The IRD concept is also to be conceived as strategic design of problem solving planning process for the effective involvement of local human and physical resources to improve the socio-economic and ecological situation of the rural habitat.

Abstract

The female children are equally important apart from male children of any country. It donated as Sex composition of Child population (0-6 Years), which is basic demographic characteristics. The deficit in girl children will have many implications, the most fundamental being to define the limits of the society's reproductive potentials. Further, the existing sex composition of children is also the basic demographic determinants of births, deaths and marriages in future. Moreover, future migration rates, work force and all other population characteristics can be influenced by the ratio between the sexes of children at present. The present aims to examine deficit of girl children and its causes along with upcoming consequences in India based on secondary data collected from census apart from others and suggestions are given for advocacy as well as policy matters.

Keywords: Gils Child; Discrimination; Son Preference; Neglect of Girls; Sex Selective Abortion

Introduction

In a "normal world," the female population equals or slightly surpasses the number of males. Except in India, that is, where the situation is just the opposite, where the gender ratio- or the number of females to males- is known to be among the most imbalanced in the world. Child Sex Ratio is defined as "number of females per 1000 males in the ages of 0-6 years" in given period in an area. Although China has the most severe shortage of girls compared to boys of any country in the world today, in India, the 2011 census revealed disturbing news: the proportion of girls aged 0-6 years dropped from 927:1000 to 914:1000 since the previous census done 10 years earlier. The census also revealed that the phenomenon has reached high proportions in states which had no prior history or practice of female infanticide, or where forms of discrimination against girls were not strongly evident earlier. The reasons behind this mistreatment of girls crosses the spectrum of Indian regions, economic classes, and castes and are due to a complex mix of economic, social, and cultural factors. In India, the changes in education, employment, nutrition, work patterns, religion, and culture, as well as family concerns such as marriage, property, inheritance, and continuity are the causes for imbalance sex ratio.

Though the population growth rate in respect of males was lower at 17.1 per cent, when compared with 18.3 per cent for females-implying some correction in the overall sex ratio- the child sex ratio (for the age group from zero to six years) deteriorated over the decade, from 927 to 919 females for every 1000 males. This should set off alarm bells in the government, civil society groups and the law. This ratio is mainly man-made through selective sex determination with the aim of getting rid of the girl child, early death due to neglect and infanticide. As per census of India, 2011 the declining sex ratio in India is due to "neglect of the girl child resulting in their higher mortality at younger age, high maternal mortality, sex selective female abortions, female infanticide, change in sex ratio at birth"[1] . The deficit of Girl Children is an unique feature of India over the decades as compared to developed nations, which has been highlighted in respective census repots and also studies by many authors viz,[2–4] , but many were examined the trends and causes for deficit of girl children population by examine the child sex ratios, while some[5,6] and IDRC and Action Aid India, 2011 with some efforts made on its impending consequences.

Objective

The objectives of the present paper are to examine deficit of girl children in India, it causes and future repercussions extensively along with suggestions to overcome the issues.

Methodology

The present paper based on secondary data collected from census of India and other published documents. Here the Girl Children is considered as number of female children per 1000 male children in the age group of 0-6 years in given area in a period of time.

Results and Discussion

The sex ratio worked out for population of all ages is not indicative of any clear picture to know whether it is favourable to females or otherwise. The child sex ratio generally affected by two factors namely mortality differentials and extent of medical interferences, which influence overall sex ratio also. Hence, child sex ratio is always considered as the best indicator to understand the sex ratio at birth when the data on births by sex are not easily available. Differentials in child sex ratio explain changes girl child population over period of time in India.

Table 1 depicts that Over all Sex Ratio(Number of females per 1000 males) was 945 in 1951, comedown to 934 in 1981 and recorded as 943 in 2011, implying some improvement in the overall sex ratio in recent decade; while, the child sex ratio (0-6 years of ages) deteriorated over the decade, from 983 in 1951 to 927 in 2001, thus declined sharply with 56 points in five decades and it further declined to 914 in 2011, such least had never recorded after independence.

Table 2 shows that in 1961 census, the child sex ratio at the National was 976; whereas the rural child sex ratio stands at 957 and urban child sex ratio was 951. The corresponding figures in 2011 census are 914, 919 and 902 respectively. Further, the gap in rural-urban child sex ratio was 6 in 1961, rose to 17 in 2011. Thus, the child sex ratio had been drastically declined and gap had been widened. The main causes for low child sex ratio and further decline, gap in rural-urban in the country are: Neglect of girl child resulting in their higher mortality rates at younger ages, high maternal mortality, sex selective abortions and female infanticide.

Causes

The causes for deficit of girl children in India context are many fold viz socio-economic, cultural, religious and political, which are complex in nature, most being are discussed here.

The son-preference trend in India

Apart from higher morbidity levels, which cause mortality of girl children, preference for son has been main causes for decline of girl children. Son-preference has being equally strong among different income groups and irrespective of caste and sex ratios where earlier period showed that sex ratios were better among lower castes and among the poor. The norms that have been part of India's socio-economic fabric for centuries are that Sons are considered pivotal to family welfare, as they are the ones who earn money, continue family lineage, and provide a form of old age security for parents. A daughter, meanwhile, is considered to be a "double loss" as she not only leaves her family when she marries, becoming an "asset" to her new family, but she is also a source of marriage expenses, including the payment of dowry to the groom's family.

Family planning-for sons

Some new trends, such as the two-child family norm encouraged by the Indian government, and an emphasis on education also influence decisions. However, it has been that although small families are accepted in Himachal Pradesh, Punjab, and Haryana, family planning effectively means, "Planning for sons." Generally, people want educated daughters-in law, because it "…is oriented towards the future family of the couple-children will get proper guidance and instructions from an educated mother…marriage prospects rather than employment appear to drive education." However, parents expressed the hope that more education for girls would result in them obtaining white-collar, regular, and secure work pre-marriage-and a better choice of prospective husbands. In rural areas of India, there may be a compromise in the duration of schooling. It observed that "… girls are encouraged to complete as much education as they can- but-

if a 'good match' is found; the girl is married off before she completes her studies."

Sex-selection practices

In India, members of the older generation referred to children as natures or a divine gift, and of the sin of getting rid of a child. Women of reproductive age may agree with this view, and may protest, but decisions of family member's plays crucial role regarding gender of children. Since the 1980s, technology widely available in India, such as amniocentesis and ultrasound, has permitted parents to predetermine the size and gender composition of children for their families through abortion. Although sex-selective abortion is illegal and banned in India, it has been widely practicing even rural areas of India. Some people are did not stop at one abortion, but had more than two times-because a girl had been conceived each time. "Abortion," is the method of family planning par excellence-to limit family size, to enable spacing between children, and also to regulate the sex composition of the family. Sex Selective Abortion is referred as "High-Tech Sexism" by AmartyaSen[7] a renowned economist, who studied missing females in India.

Neglect of girls

Neglect of girls, whether planned or inadvertent, also contributes to the lower child sex ratio. The degree of discrimination varied by location, there nonetheless was widespread evidence of lower levels of nutrition, health care, schooling, and emotional care, and high levels of under immunization in general. "With nutrition and health, who may or may not take the decision is uncertain, but the discrimination is evident". A firstborn daughter was not typically subjected to inferior treatment; she was treated like her brothers. But with each additional girl, the pressure to have a son increased and starts discrimination against girl children.

Dissatisfaction of Daughters

When a daughter grows up and marries, she essentially becomes chattel in her husband's parents' home and has very limited contact with her natal family. Even if she earns a good living, it will be of no help to her own parents in their old age. So for parents, investing in a daughter is truly, in the Hindi expression, planting a seed in the neighbor's garden. Sons, by contrast, provide a kind of social security. Changes in work, education, marriage age, and marriage costs also seem to add up to disaffection for daughters, to a greater extent than before. The factors causing this include: increased investment that has to be made in daughters in terms of education and marriage; the loss of their material and labour support; fears for their sexual safety and security; and worries about their future happiness in an appropriate marriage.

Impending consequences: In India, the deficit of Girl Children leads to many severe upcoming consequences by way of socio-economic, cultural, religious, demographic, and political aspects, but many may be less gravity and some could be very serious, which are briefly discussed hereunder.

No relevance of institution of marriage: Continuous declining in Child Sex Ratio has many potentially serious consequences, although there are no historical model by which to learn about the implications of a lack of women relative to men, one fairly obvious social consequences is that there are not enough women for men to marry and the institution of marriage would lost its relevance.

Raise in Child marriages: The scarcity of brides might lead to the child betrothal and early marriage (child marriage) to cope with the problem. Increasing numbers of child brides will further contribute to the poor status of women, as will be less likely to finish the school or develop skills before

marriage.

Chances of Disease Burden: Young brides and their children are also more likely to suffer from the increased morbidity and mortality associated with early child birth Thus there are serious socio-economic and health implications of declining child sex ratio.

Increase in dowry Amount : Another consequence of scarcity of female is the increase in dowry i.e. payment of exorbitant dowry, daughters are often sold to higher castes and even poor man often paid a bride price to obtain a wife. Among the Jats in particular and various other in general, the scarcity of women led to wide spread system of polyandry.

Non available of suitable spouse by age and sect: Present trend of gender imbalance continues, one of the serious repercussions would be a rude shock to the institution of marriage in the decades to come. It has severe consequences especially in North Indian states of Punjab and Haryana which are characterized by in ability of men in marriageable age to find suitable partner by age as well as caste.

Increase in age gap: Scarcity of females may cause to increase in age gap between bide and bridegrooms. The brides will have much lower ages than bridegrooms, it causes to many problems like adjustment, family life, companionship etc.

Buying brides from other regions : The Hindustan Times, July 12, 2003read as "in Hathin (Haryana), because of shortage of women men buying brides from other states like Assam, West Bengal and from far away villages of Bihar. The price put on such a girl is much less than what people pay for cattle, after marriage they are condemned to a life of slavery.

Cultural Problems: Men from the shortage of female by caste, group, area and region causes to get marry of other castes, sects, areas and regions, it may causes to cultural problems, because brides have to adjust with bridegrooms family cultural, deviation may causes troubles in coping up of family life.

Abduction and trafficking of girls: Shortage of brides would be leads to abduction and trafficking of girls that resulted in expansion of the sex industry with the magnitude of spreading Sexually Transmitted Diseases and deadly disease like HIV/AIDS would increase manifold. The Hindustan Times recently reported that young girls from Assam and West Bengal are kidnapped and sold into marriage in neighbouring Haryana [8] .

Raise of anti-social behaviour: In this distorted social scenario marked by growing anti-social behaviour, crimes against women like rape, molestation,eve teasing, child marriages; forced polyandry etc. is also expected to rise.

Pressure on Women: Parents who have a fervent preference for male offspring will impose pressure on women. Thus, women who had given birth to only daughters were desperate for sons and would keep having children until they had one or two male children. In a study done by the Centre for Social Research in Haryana, fear of violence is a cause for female foeticide. Also the women who produce daughters face much more domestic violence which makes them complicit in getting rid of the girl child [9] .

Risk of ostracism: A family with only daughters will also likely lose its land when the father dies: although women can legally inherit property, in some areas of India, they risk ostracism or even murder if they claim what is theirs.

Some men may remain unmarried : Some states now experience a shortage of brides because of the adverse sex ratios. It was notes that 20% or more men in some states, including Haryana and Punjab, may remain unmarried. There are already examples of brides being "imported" from poorer eastern states. Further, unmarried men may faces Psycho-social problems like lack of sexual pleasure, family life, loneliness etc.

Delay in Marriages: Trends to higher age at marriage, more so in urban settings, were also observed, possibly as a function of the emphasis on education. In urban areas, it observed that the average age at marriage is now 20 for boys and 17 to 18 for girls, where earlier both were married at 14 years of age. Perhaps the rise in marriage age may be due to greater difficulty in finding an eligible spouse, with factors such as education, earning capacity, and dowries raising the stakes for the ideal match.

Choice of mate selection by girls may decline: Ensuring a girl's chastity is considered a great parental responsibility and is one of the arguments for promoting early marriage. For better or worse, some of the usual social, cultural, and economic norms in Indian society's choice of mates may be swayed. In some regions inter-caste marriage, marriage with girls of tribal communities, and polyandry are now becoming more common.

Social tensions arise: There are also reports of bride buying and forced remarriage of widows. In the near future social tension could rise because of the challenge of finding female partners, and may lead to crimes against women. Others wonder if a shortage of women will lead to less violence against them, or a decrease in dowries. Thus, the increasing imbalance in sex ratios is a sign of continued inequality between the sexes. The scarcity of females, they add, is symptomatic of their low value.

Disappear of mothering roles: In India, females are playing crucial role in household chores, childbearing as well as child rearing activities with more patience. Further, females role as mother cannot be ignored that strengthens family system;welfare of family members; however, in future, these can be slowly disappear if girl children decline rapidly.

Decline in Female labour: Apart from household works, females are engaging in outdoor employments, especially in agrarian sector of rural economy, the contribution of females by supporting men has been quite significant. However, their contribution is often unrecorded and unacknowledged. In

this context, decline in child sex ration leads squeezed female labour force. Further, the economic consequences are grave for deficit of females that a huge proportion of the productive population is missing and also the lack of women impairs the ability of men to work.

Decline Population Growth: In the entire world, for smooth growth of population of any county, both men and women are equally important. If females continuously declining, it causes to deficit of women population thereby it affects the growth of population by lack of females for men reproductive activity. Thus, scarcity of females brings down societies reproductive potential by lowering net reproductive rate. Moreover, events such as new household formation will decline.

Conclusion

Now a days, in a patriarchal society like India, a daughter is generally unwelcome due to "Guarding her chastity", as well as expenditures by way of Dowry are a heavy burden on parents apart from worry on uncertainty of her life after marriage. A son on the other hand continues the family line, provide the parents with emotional and financial security and perform the last rite i.e. male child is important for moksha. These are major cause apart from other reasons for rapid decline in child sex ratio in recent decades. Though, in India the acts are passed (such as The Prenatal DiagnosticTechniques Acts, 1994, The dowry prohibition Act), however these Acts are not properly implemented. It may be therefore, concluded that effective enforcement of laws along with softening a son-centered culture and bringing changes in cultures that are deeply rooted by way of socio-economic, and religious concerns which are causes for discrimination of girl children. Moreover, balanced child sex ratios are essential to avoid upcoming evil consequences of deficit of girl children in India.

Solutions and Advocacy

The long-term and short-term measures can stem to supersede from the deficit of girl children in India. In the long term, it is suggested that ensuring equal entitlements such as property rights, equal access to nutrition, health, education, affection, guarantee on safety and addressing the problem of dowry and life after marriage. While, in the short term, incentives to educate girls, financial support for girls, educating healthcare professionals and enhancing incentives for more number of female children born are recommended. "Another option is depositing some amount of cash to families where there are one or two female children in a household and no male children for future expenses such as education, marriage and life security. Such innovations are being started now in small settings in different places of India."

The development and focus aid on women are the two aspects that can tackle the declining girl population in India. The development can surely the wealthier the home, the more educated the parents, the more plugged in to the modern economy, the more a family will invest in its girls. But these efforts should be joined by an awareness of the unintended consequences of development and by efforts, aimed at parents; to weaken the cultural preference for sons. The other is focusing aid on women. The idea is that a mother who has more money, knowledge and authority in the family will direct her resources toward all her children's health and education. She will fight for her girls. While increasing women's decision-making power would reduce discrimination against girls, "When women's power is increased, prejudices and cultural practices opposite to girl children can decline".

In Indian context, it will not be enough to counter son-preference. But, dislike to daughters has to be evenly provoked through policy measures that increase the economic worth and support of daughters through improved employment opportunities, recognizing women's health and emphasizes on education levels than the mothering roles.

Finally, understand the formal and informal social, cultural, economic, and political processes that motivate the bias against having female children are needed to frame social policies to overcome a long-standing cultural preference for male children and to reverse a potentially disastrous future imbalance in the male/female child ratio of India's population.

Abstract

Housing plays a crucial role in the lives of individuals within any society. House ownership has traditionally been highly valued, seen as essential for family stability and wealth creation. The quality of housing, including access to basic amenities like water, sanitation, electricity, and more, is a significant indicator of a country's socio-economic development. Housing with basic necessities is a fundamental factor in economic, social, and civic progress, with various housing-related activities directly contributing to broader development objectives. When individuals and families do not have adequate housing with better characteristics, their well-being is severely affected. Inadequate housing can lead to poor health outcomes, placing a strain on the healthcare system. This study utilizes a descriptive research design, analyzing secondary data from the National Family Health Surveys (N.F.H.S) 1 to 5, to explore housing characteristics patterns in India and its states.

Keywords: Electricity; Drinking Water; Toilet; Fuel for Cooking; Pucca House and Persons Per Room

Introduction

India is home to a staggering 300 million individuals who endure extreme poverty and grapple with the lack of basic necessities such as food, clothing, and shelter. These individuals face the harsh reality of living in homes that lack essential services like water, sanitation, electricity, healthcare, and education **(Millennium Development Report, 2014)**. The provision of basic amenities in housing is crucial not only for improving the socio-economic status and standard of living of households, but also for fostering sustainable development. The absence of basic amenities within households, highlights the exclusion of a significant portion of the population from essential social infrastructures. In light of this, Rabiul Ansary and Bhaswati Das[(1)] argue that the denial of basic amenities like clean fuel and electricity will hinder India's efforts in controlling pollution and addressing issues such as climate change. The National Family Health Survey (N.F.H.S) offers insights into the demographic and socio-economic characteristics of households, shedding light on key housing aspects of the population. Understanding household characteristics and housing conditions provides valuable context for comprehending the socio-economic, demographic, and health situation of the population.

The study of housing and its characteristics serves as a reliable means of expressing human responses to the physical and cultural environment of a region. It represents the cultural achievements of the past and the preservation of traditions through simple architectural features. The housing conditions of families directly reflect their socio-economic and cultural status.

In typical human settlement patterns, there is a noticeable disparity in the types of houses occupied by different families. Affluent upper caste families reside in elaborate houses equipped with excellent all facilities, showcasing their social, cultural, and economic status. On the other hand, lower caste families find shelter in small houses or huts with inadequate basic facilities. Housing Characteristics like drinking water, bathroom and toilet facilities are essential to maintain one's good health and productivity. It is often argued that good housing conditions are essential elements for enhancing household health, and that poor housing and environmental conditions can lead to many health problems, including infectious diseases (such as tuberculosis and malaria), stress and depression (Udofia, Yawson, Aduful, & Bwambale, 2014). Zihan Kan et al[2] study results indicate that communities with relatively poor housing conditions have impact of housing on mental health may be more direct; while, for communities with relatively good housing conditions, the effect of housing characteristics on mental health may be indirect. The quality of life of any households in a region (state) is largely determined by availability of safe drinking water, sanitation, drainage facility for waste water, type of fuel used for cooking purposes and availability of separate kitchen, congestion of the households[3]. Availability of basic amenities within households is also another proxy indicator to study multi-dimensional deprivations and social inclusion or exclusion of a population. In many villages of India, the practice of untouchability still forces people belonging to a particular caste to fetch water from long distances[4].

Review

Bhagat et al. (2018)[4] conducted a study that focused on housing characteristics in nine villages located in the Melghat areas of Maharashtra and these areas are known for their high levels of poverty and malnutrition. In a study by Ibrahim Yakubu et al.[5], the link between housing conditions, resident health, and poverty levels was explored in the Metropolitan area. The findings revealed that a majority of houses in this area lack essential in-house facilities. Wei Guo[6] found that housing type and size have a significant impact on the health of migrants, while housing instability has a greater effect on the health of urban locals. Maria Löfstedt[7] conducted a new case study that reviewed the relationship between physical housing characteristics, housing accessibility, and various aspects of health among older people living in the community. Coley et al.[8] conducted research that demonstrated how poor housing conditions negatively affect the development of children and adolescents. Dekker et al.[9] concluded that individual characteristics such as age, presence of children, and length of stay are more influential in explaining residential satisfaction than specific estate characteristics. In a study by Daan Schipper[10], it was found that various socio-demographic variables have a significant impact on subjective well-being in relation to housing characteristics, as well as certain economic activities. Esraa A. Attia[11] aimed to reveal the relationship between rural housing characteristics and social-economic variables for the heads of families residing in these areas. Rabiul Ansary and Bhaswati Das[1] concluded that households lacking good housing conditions and basic amenities, which are essential for healthy and productive manpower, tend to have lower assets.

Objective

The paper aims at examine the pattern of housing characteristics in India and its 30 states based on secondary data during the period of 1992–93 of N.F.H.S-1 to 2019-21 of N.F.H.S-5.

Methodology

The research paper utilizes a descriptive research design and relies on secondary data obtained from the National Family Health Survey (N.F.H.S) conducted over a span of 38 years, from 1 to 5. The housing characteristics examined include electricity, drinking water, toilet/latrine facility, solid fuel used for cooking, pucca house, and the mean number of persons per room used for sleep. The N.F.H.S-1, conducted in 1992-93, encompassed 88,562 households. In 1998-99, the NFHS-2 survey included a representative sample of 91,196 households. NFHS-3 collected information from a nationally representative sample of 109,041 households in 2005-06, while N.F.H.S-4 in 2015-16 selected 628,900 households. Lastly, the NFHS-5 survey of 2019-21 covered a total of 636,699 sample households.

Results and Discussion

Housing characteristics data can be used as an indicator to address statistically how many people from various states have been excluded from an adequate standard/quality of living. The pattern of households' dwelling characteristics has been captured by seeing the condition of residential houses, types of house structures, the number of rooms a household possesses and other basic amenities such as electricity, drinking water, toilet/latrine facility, and percent of solid fuel used for cooking and these basic household amenities are discussed briefly hereunder.

Electricity

Electricity plays a crucial role in the daily lives of humans and is a significant factor in the modern economy. It is utilized for various purposes such as lighting, heating, cooling, refrigeration, operating appliances, computers/electronics, machinery, and transportation systems. Yunqing Lu et al.[12] conducted a study on energy consumption and household characteristics by implementing a dynamic pricing experiment in communal housing within a smart community in Japan. Table 1 illustrates the distribution of households with electricity in India and its states.

Table 1 reveals those substantial variations in households with access to electricity during the period of N.F.H.S-1 to N.F.H.S-3. However, access to electricity drastically improved in India and its states in the period of N.F.H.S-4 and N.F.H.S-5. In most states, over 95 percent of sampled households have electricity and almost all households in India (97%) have electricity in N.F.H.S- 5 of 2019-20. It clearly indicates that sampled households had electricity for many purposes in their homes to lead better life.

Drinking water

The provision and availability of safe drinking water and sanitation plays a crucial role in enhancing the quality of life and promoting good health. It helps in reducing illnesses, water-borne diseases, and fatalities, leading to lower health expenses, increased savings, and enhanced human efficiency. In rural areas, women or girls are typically tasked with fetching water from various sources for household purposes. The accessibility of water was a key aspect of the Minimum Need Programme initiated between 1974 and 1979 to cater to all segments of society. Ensuring access to clean and safe drinking water is essential for overall health and well-being. In certain states like Manipur, Odisha, Meghalaya, Tripura, Jharkhand, and Madhya Pradesh, around 33 percent of households, and in states like Nagaland, West Bengal, Chhattisgarh, and Rajasthan, approximately 25 percent of households, obtain water from sources located away from their homes[3] . Drinking water serves various vital functions in the body, such as regulating body temperature, maintaining healthy skin, and aiding in digestion (Duselis, Amanda R et al., 2007 and Amend, Sarah R et al., 2016). The National Family Health Survey (N.F.H.S) recognizes improved sources of drinking water, "including piped water, public taps, standpipes, tube wells, boreholes, protected dug wells and springs, rainwater, and community reverse osmosis (RO) plants". These sources help safeguard against external contamination, ensuring that the water is safe for consumption.

Table 2 reveals that significant percent of households had increaseaccess to improved source of drinking water in India and its states during the study period. In N.F.H.S-1, only over 40.0 percent access to improved source of drinking water in states like Assam, Manipur, Meghalaya, Mizoram, Tripura and Kerala being with least 21.0 percent) wherein most of the households get drinking water from open well with the premises of house in general., over 80.0 percent and 90.0 percent of household have access in most of the states and in India in N.F.H.S-3 and N.F.H.S-4 respectively. However, in most of the states and in India, over 95.0 percent of households have access to improved source of drinking water in N.F.H.S-5. This clearly indicates that most of people are protected from water born diseases with having access to improved source of drinking water.

Toilet facilities

According to the World Health Organization, open defecation is considered the most dangerous sanitation practice. Nearly 10 percent of all communicable diseases are associated with unsafe water and inadequate sanitation. In 1986, the Government of India initiated the Central Rural Sanitation Programme (CRSP) to enhance sanitation coverage in rural areas, aiming to improve the health and quality of life of rural residents, especially women, by providing privacy and dignity. The Total Sanitation Campaign (TSC), a variant of CRSP, was introduced in 1999 with a community-driven and people-centric approach. Despite efforts to achieve the MDG Goal of 'Sanitation for All' by 2012, the TSC programs fell short. The 2011 Census revealed that almost half of Indian households (49.8 percent) practices open defecation, with 53 percent lacking toilet facilities in their premises. A study by[3] based on the 2011 Census indicated that central Indian states have higher rates of open defecation compared to the rest of the country. While a significant portion of the population lacks household toilets, a majority own mobile phones. Cultural norms, traditional beliefs, lack of awareness, and low education levels are cited as the main reasons for this unhygienic practice[1]. The National Family Health Survey (N.F.H.S) defines toilet facilities as "any non-shared toilet types, including flush/pour flush toilets connected to piped sewer systems, septic tanks, and pit latrines; ventilated improved pit (VIP)/biogas latrines; pit latrines with slabs; and twin pit/composting toilets".

Table 3 depicts drastic improvement in households with any toilet facility in India and its states duringof N.F.H.S-1 of1992-93 and N.F.H.S-5 of 2019-20. In N.F.H.S-1, less than 25.0 percent of household have access to toilet in states like Himachal Pradesh, Jammu & Kashmir, Rajasthan, Madhya Pradesh, Uttar Pradesh, Bihar, Odisha and Andhra Pradesh. About 30.0 percent households have no toilet facility in state like Himachal Pradesh, Rajasthan, Madhya Pradesh, Uttar Pradesh, Bihar, Odisha and Andhra Pradesh in N.F.H.S-2, while significant percent of households had access to toilet facility in majority of the states and in India during the period of N.F.H.S-3 and N.F.H.S-4. However, less than 25.0

percent of household had not having toilet facility in states like Rajasthan, Madhya Pradesh, Uttar Pradesh, Bihar, Odisha, Gujarat, Maharashtra, Andhra Pradesh, Karnataka and Tamil Nadu in the period of N.F.H.S-5, it causes to practice open defecation. No access to sanitary toilet provisions led to no ensure of hygiene conditions. It reveals the extreme conditions that exist in these states there by riskiest sanitation practice may causes to water and air born diseases that leads ill health of people.

Use of solid fuel for cooking

Exposure to indoor smoke, whether from cooking with solid fuels or smoking tobacco, can have adverse health effects. The risk of exposure to cooking smoke is higher when cooking is done indoors rather than in a separate structure or outdoors. India faces a significant challenge in providing safer cooking fuel options. The United Nations' efforts to combat extreme poverty may not reach their full potential unless countries prioritize bringing electricity and modern, safe cooking technologies to the billions of energy-poor individuals worldwide[13]. Majority (71.5 percent) of

households in India still rely on firewood, crop residue, cow dung cakes, or coal for cooking, which are common traditional fuels in rural areas[1]. It is estimated that up to 70 percent of households in developing nations use wood, dung, and crop residues for cooking (International Energy Agency, 2002). The National Family Health Survey considers solid fuels for cooking to include "coal/lignite, charcoal, wood, straw/shrubs/grass, agricultural crop waste, and dung cakes".

Table 4 reveals the substantial variations across in India and states in households with usedsolid fuel for cooking. Significant percent of households had used solid fuel for cooking during the period of N.F.H.S-1 and N.F.H.S-4 in India and many states. Even in N.F.H.S-5 period also, over 50.0 percent of households used solid fuel for cooking in India and its many states. Hence, burn of solid fuel for cooking causes to harmful air pollution that leads health impact on lungs related diseases especially among women and children.

Type of House

Houses owned by the wealthy are considered 'pucca', indicating that they are constructed using durable materials such as stone, brick, and cement. On the other hand, the houses

of the poor are categorized as 'Semi katcha' or 'katcha', as they are built using less durable materials like country tiles, stone rubbles, mud, and thatch, which are readily available locally. In rural areas of India, the design of houses is influenced by the availability of local building materials. The construction of houses in rural settings aims to fulfill the functional needs of the families residing in them. Approximately 12 percent of residential structures in India are temporary in nature. The eastern and central regions (West Bengal, Odisha, Bihar, Jharkhand, and Chhattisgarh) have a higher percentage of dilapidated houses used for residential purposes, while the southern and western states report the lowest percentage [1]. According to the National Family Health Survey (N.F.H.S), "pucca houses are those constructed using high-quality materials for the floor, roof, and exterior walls".

Table 5 reveals the substantial variations in households living in a pucca house in India and its states during the period of N.F.H.S-1 to N.F.H.S-5 and majority of households were not lived in pucca houses in many states. However, an improvement was observed in percent of households living in a pucca house in India and its states during the period of N.F.H.S-1 to N.F.H.S-5 due to construction of pucca for socio-

cultural and economically marginalized by the governments under housing schemes. But still in N.F.H.S-5 period, 30.0 percent in India and over half of sampled households were not living in a pucca house in the states like Madhya Pradesh, Uttar Pradesh, Bihar, Arunachal Pradesh, Assam, Manipur, Meghalaya and Tripura. This clearly indicates that significant percent of households not had living in a pucca house in India and its states due to poor socio-economic, cultural and geographical reasons though pucca house is being the one of basic need of human being to live comfortably.

Person per room

The measure of crowding known as ”persons per room” takes into account all the rooms in a private dwelling and the number of people living in the household. A higher value for ”persons per room” indicates a greater level of crowding. In India, approximately 3.9 percent of households do not have rooms specifically designated for residential purposes [1]. According to the Census 2011 data, there are 43,813 families living in shared rooms, with nearly 40,000 of them located in urban Delhi. This data clearly highlights a significant proportion of the lower middle class residing in shared rooms

within the city's population.

Table 6 reveals the significant variations across in India and its states in mean number of persons per room used for sleeping during N.F.H.S 1 of 1992-93 to N.F.H.S-5 of 2019-21. On an average 2.5 mean number of persons per room used for sleeping in India and in many states. However, over 2.5 mean number of persons per room used for sleeping in states like Delhi, Haryana, Himachal Pradesh, Punjab, Rajasthan, Madhya Pradesh, Mizoram, Maharashtra, AndhraPradesh, Kerala Andhra Pradesh, and highest being 3.0 mean number of persons in Uttar Pradesh, Bihar, Gujarat in N.F.H.S-5 period. In states with higher mean number of persons per room used for sleeping can be problems such as individual privacies, congested and health issues especially such as the period of Covid-19 etc.

Conclusion

Drastic improvement had observed in house hold electricity and improved source of drinking water during the period of N.F.H.S-1 to N.F.H.S-5. All most of sampled households' access to have electricity (97%) and over 95.0 percent of households have access to improved source of drinking water in India and its states in N.F.H.S-5. However, less than 25.0 percent of household had not having any toilet facility in states like Rajasthan, Madhya Pradesh, Uttar Pradesh, Bihar, Odisha, Gujarat, Maharashtra, Andhra Pradesh, Karnataka Tamil Nadu and Telangana in the period of N.F.H.S-5. Substantial variations have observed across in India and its states in households with use of solid fuel for cooking. Over 50.0 percent of households used solid fuel for cooking in India and its many states. This could lead to lungs and heart diseases. Over 2.5 mean number of persons per room used for sleeping in states like Delhi, Haryana, Himachal Pradesh, Punjab, Rajasthan, Madhya Pradesh, Mizoram, Maharashtra, Andhra Pradesh, Kerala, Andhra Pradesh, Telangana and highest being 3.0 mean persons per room used for sleeping observed in Uttar Pradesh, Bihar and Gujarat, can be cause to problems such as personal and health. Therefore, the N.G.Os and govern agencies should make better inclusive policies related sanitation/toilet, clean fuel for cooking and pucca house for poor/ marginalized sections that are the highest level of deprivation and contributing to poor health, high mortality and low quality of living.

ABSTRACT

Agricultural regionalization is a process of Delineating on area in to territorial units of complexes of uniformities on the basis of physical factors like climate, soils, vegetation, and availability of water, farm size and socio-economic parameter. It has a significant bearing on the development of agricultural and regional planning in developing countries. It is needed to understand Agricultural types, variations, challenges, forecast productivity, feature plans for agricultural developments, suggest optimal land utilization patterns, and make an inter-regional comparison in different aspects and so on. Agriculture is one of the leading occupations in India. It is back bone of Indian economy. In India nearly about 64 % of the total population and 90 % of rural population is engaged in agriculture. India being a country of Intensive subsistence farming activities are observed all-round the year in various intensities. Understating the importance of regionalization, specifically crop regions; an attempt is made in the present study, to demarcate the crop regions of Kurnool district for two time periods i.e., 2007-08 & 2018-19.

Keywords : *Primary crop region, Secondary crop region, Tertiary crop region Ranking Method, and Change of crop regions***.**

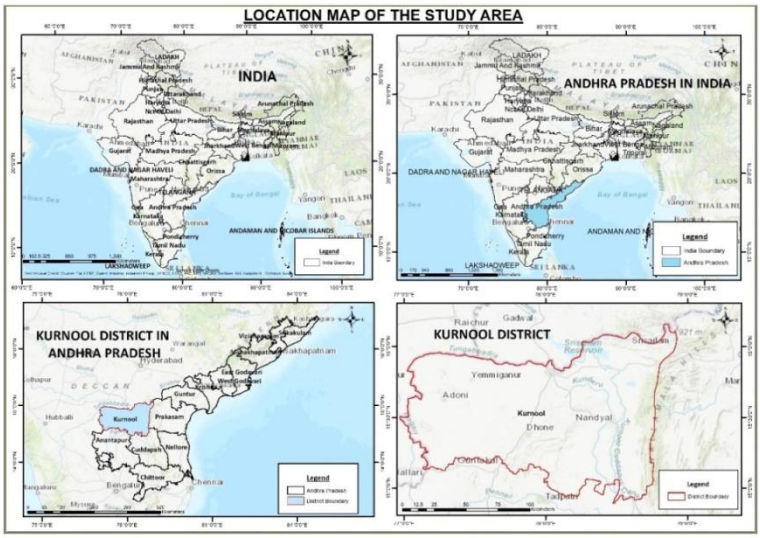
INTRODUCTION

Agriculture is an important occupation which is considered as a part and parcel

of human life and which runs through a definite process. It is carried under the control of natural environment. Agriculture is an important source of food. In spite of growing industrialization and urbanization in the world. In developing countries agriculture sector has been a major source of employed and income. Agriculture is a backbone of Indian economy. In India near about 64 % of the Total population and 90 % of rural population is engaged in agriculture. In spite of technological development, environmental factors play key role in the Development of agriculture in the region. Socio-economic factors also support for the growth of agriculture. This it is necessary to focus on the physical and Socio-economic Factors of the study region to understand the agricultural scenario of the region.

Agricultural regionalization is one of the oldest concepts in Agricultural classification and has a significant bearing on regional planning and development of agriculture in developing countries. It is regarded as a device for clustering both visible and non-visible Agricultural phenomena on the earth surface. Such device enables geographers to divide an area in to several regions in terms of diversity present in agricultural system. It gives us the relative position of crops on regional scale (Dayalan N.2018). The analysis of general land use, agricultural regionalization and cropping pattern helps to denote the intensity and status of farming in an area and also helps in the formulation of Agricultural plans which may go a long way in reducing the regional disparities and inequalities.

Systematic study of crop regions is of great significance for a comprehensive and clear understanding of the agricultural mosaic of an agro-climatic region and the planning and development of its agriculture, in recent years the concept of crop regions has engaged the attention of geographers and agricultural land use planners.



The first attempt of agricultural regionalization of Europe was made by *Jonsson* (1926) in his work Agricultural regions of Europe. Baker (1926), one of the Leading American Geographers, published Agricultural regions of North America, and Jones (1928) produced his book Agricultural regions of South America. Similarly, Taylor (1930) Delineated agricultural regions of Australia and Valkenberg (1931) divided Asia into Agricultural Regions. The first attempt to classify types of agricultural land use the world over, in terms of agricultural element – complexes, was in the form of the empirical system developed by Jones and Whittlesey (1932). A few of Russian authors who have put forwarded their views regarding Agricultural regionalization, Marshall (1787), Arsenev (1818), (Raktinika, 1959, 1971, 1973, 1975, 1979). Others have attempted to demarcate regions by aggregation of basic areal units based on agriculture with the help of quantitative taxonomic methods (Hartshorne and Dicken 1935, Nordgard 1974).

In India, geographers richly contributed to the studies of agricultural geography on various aspects including cropping intensity, crop combinations, crop concentration, crop diversification, agricultural efficiency, agricultural classification, agricultural regionalization, agricultural typology of which brought about lot of changes in the subject matter, approaches and methodology of agricultural geography. Deshpande (1942, 1964), Mukherjee (1942), Dayal (1950) etc. made regional studies in agricultural geography. Chatterjee (1952, 1956), Shafi (1960), Singh (1962), Bhatia (1967), Mishra (1969), Raifullah, Jasbir Singh (1972) etc. are among the notable agricultural geographers in India.

LOCATIONAL SETTING OF KURNOOL DISTRICT

Kurnool district is the south-western district of Andhra Pradesh and lies approximately between 14º54' to 16º18' North Latitudes and 76º58' 79º34' East Longitudes. The altitude of the district varies from 100 ft above the mean sea

level. This district is bounded on the north by Tungabhadra and Krishna River as well as Mahbubnagar district, on the south by Kadapa and Anantapur district, on the west by Bellary district of Karnataka state and on the east by Prakasam District. The district ranks 10 in population with 40, 53,463 people accounting for 4.63 % of the total population of the state as per 2011 Population census. While in area it occupies the 3rd place 17658 sq.km. which account for 6.41% of the total area of the state. The Nallamala and Earramalla are two important mountain ranges in the district running in parallel from North to south. Earramla divided the district into two well defined tracks from east to west in terms of soils. The Kurnool District is a combination of Red, Block and sandy soils. It has facility of Irrigation through canals (K. C. Canal, Tungabadra project low level canal and hundri neva sujalasravanthi project), tanks, wells, and river sources. The district has typically geographical aspects and climatic variation comparatively from other districts of Rayalaseema region of Andhra Pradesh. The district is well connected with road and rail transportation with national highways to farmer capital city of Andhra Pradesh.

OBJECTIVES

To identify and demarcate the crop regions such as primary, secondary and tertiary crop regions of Kurnool district for the years 2007-08 and 2018-19.

To study the changes in crop regions during 12 years period.

DATA AND METHODOLOGY

In the present study, secondary data pertaining to general cropping pattern for two time periods i.e., 2007-08 and 2018-19 have been collected from the Government records and reports from the Chief Planning Officer, Handbook of Statistics, Agricultural Department of Kurnool district taking 'Mandal' as Unit. Simple statistical techniques such as percentages and averages have been used to analyze the data. The spatial patterns of various crops that ranked from first to third in percentage of total cropped area is attempted here for the study of Primary, Secondary and Tertiary crop regions. The task of the first order crop regions (or) first ranking crop regions is accomplished by considering the crops which account for the maximum percentage of the total cropped area in each of the component areal units, no matter what percentage it occupies in the total cropped area. In the same way, the second-order crop regions and third-order crop regions have been demarcated on the basis of their percentage in order. To fulfill the set objectives, percentages of different crops that are growing in the district have been calculated and arranged in descending order, to demarcate the crop regions.

PRIMARY CROP REGIONS (2007-2008)

During the study period, out of 10 crops, only four crops namely Pulses (22 mandals), Ground nut (13 Mandals), Sunflower (10 mandals) and Paddy (8 Mandals) were registered as primary crops in different mandals with different concentration and one mandal srisailam which is in north eastern part of the district is 100 % covered with forest. Pulses occupied first place in the Maximum no of mandals and paddy crop in the minimum no of mandals in the district.

PULSES REGION

Pulses crop is dominant primary crop region in the study period occupying in

the district. It formed the largest region as primary crop. Pulses are one of the important food crops globally due to their higher protein content. Pulses are an important group of crops in India which is also responsible for yielding large financial gains by amounting to many exports. Pulses form an integral part of the Indian diet provides much needed protein to the carbohydrate –rich diet. India is largest producer of pulses in the world. In India the main regions with high productivity are Punjab, Haryana, western UP, West Bengal Delta region, Coastal A.P, Tamil Nadu, Kerala, Coastal and eastern Karnataka, and some parts of Maharashtra. In Kurnool it occupied about 269832 Hectares. In about 22 mandals of the district spread over in most of the south western, south-eastern, north-eastern part of the district. (Table 1 & Fig. 1).

GROUNDNUT REGION

Groundnut crop is the second –largest crop region in the study period occupying 13 mandals of the district. Groundnut is a leguminous plant that is widely cultivated in the tropics and subtropics. It is valued for its high oil edible seeds and as such, it is the fourth most important source of edible oil and a third most important source of vegetable protein and an important agricultural export commodity. In India, after Gujarat, Andhra Pradesh occupies 2nd place in groundnut production. In the actual area, it occupied about **236972** hectares. In About 13 Mandals of The district, Namely C.Belagal, Dhone, Bethamcherla, Veldurthy, Krishna Giri, Peapully, Kosigi, Pedda Kadubur, Yemmiganur, Pattikonda, Devanakonda, Tuggali, Gonegandla, mostly confined to the central, south and north western part of the district (Table 1 & Fig. 1).

SUNFLOWER REGION

Another important primary crop region in Kurnool District is sunflower spreading over 10 mandals. In the actual area, it occupied about *157104* hectares. The mandals where the sunflower region is dominant as the primary

crop region are Kallur, Kodumur, Atmakur, Kothapalle Gadivemula, Adoni, kowthalam, Nandavaram, mantralayam, Holagunda mandals, which are located in western, north, north eastern part of the district. (Table 1 & Fig. 1)

PADDY REGION

As primary crop region, paddy crop spreading over 8 Mandals, namely Velogode, Pamulapadu, Nandayala, Mahanandi, B. Atmakur, Rudra varam, sirvella, Gospadu which are distinctly seen in the eastern part of the district in Andhra Pradesh, it is mainly cultivated in the Krishna, Guntur, Kurnool, Nellore Prakasham, and twin Godavari district Kurnool sonamasoori rice is popularly fine rice variety being cultivated in Rayalaseema, especially in Kurnool due conductive atmosphere. (Table 1 & Fig. 1).

PRIMARY CROP REGIONS (2018-2019)

During the year 2018-19, 5 crops have been noticed under primary crop region in Kurnool District. They are cotton (17 Mandals), Pulses (15 Mandals), paddy (9 Mandals), millets (8mandals), Ground nut (4 mandals).

COTTON REGION

In 2018-19 cotton crop is dominant primary crop region. Cotton is one of the most important fiber and cash crop of India and plays a dominant role in the industrial and agricultural economy of the country. It provides the basic raw material (cotton fiber) to cotton textile industry. Cotton in India provides direct livelihood to 6 million farmers and about 40 - 50 million people are employed in cotton trade and its processing. In India, there are ten major cotton growing states namely Punjab, Haryana, Rajasthan, Madhya Pradesh, Maharashtra, Gujarat, Andhra Pradesh, Telangana, Karnataka, and Tamil Nadu.

Cotton region is newly formed primary crop region during the period 2018-19 replacing the sunflower, ground nut and pulses crops. The actual area it occupied in this district about 259498 hectares and spread over 17 mandals especially located in Western and northern part of the district. It is emerged as the largest crop region in the study is during 2018-19. (Table 1 & Fig. 1)

PULSES REGION

This is 2nd largest crop regions occupying the 15 mandals during the study period, confined mostly to the north, south, south eastern part of the district. (Table 1 & Fig. 1)

PADDY REGION

As a primary crop region, paddy crop is reported 9 mandals of the district, especially located in eastern part of the district. (Table 1 & Fig. 1)

MILLETS REGION

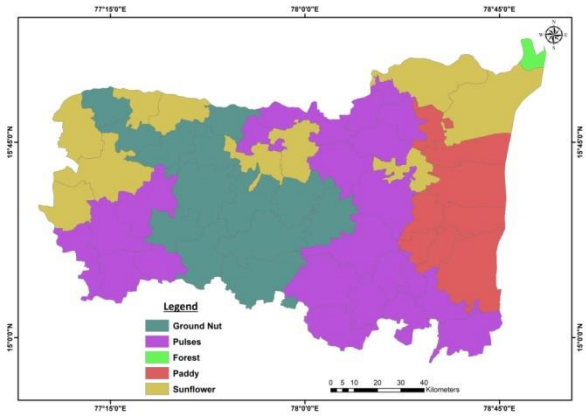
Eight mandals namely Pagidayala, Jupadubunglow, Atmakur, Pamulapadu, kothapalle, Gadivemula, Allagada, Chagalamari are reported as primary crop regions with millets in the Study period (Table 1 & Fig. 1).

GROUND NUT REGION

Ground nut as a primary crop region has been noticed in only four mandals namely Dhone, Krishna giri, Devanakonda, Tuggali located in central part of the district. (Table 1 & Fig. 1)

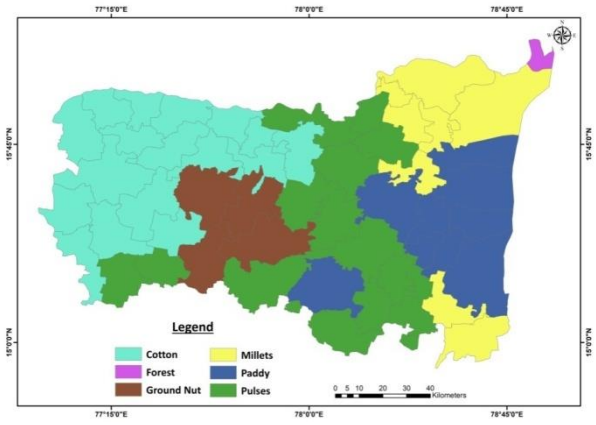
CHANGE IN PRIMARY CROP REGIONS (2007-08 & 2018-2019)

Noticeable changes have occurred in primary crop regions of the district during 12 years' period. Among the 4 primary crop regions which are registered in 2007-08, namely pulses, groundnut, sunflower, and paddy have been noticed.



After 12 years' period, new crops Cotton and millets were registered. The other changes are, increase in the number of mandals regarding paddy crop region (+ 1 mandals). A decrease in the number of mandals has been seen in the pulse's region (-7mandals) and ground nut region (-9 mandal) and sunflower crop remarkably decrease and not registered in 2018-19. New regions i.e., the Cotton and Millets regions have emerged with 17 and 8 mandals that previously belonged to the sunflower, groundnut and pulses region (Fig. 1 & Table 1).

Table – 1



Primary crop regions in Kurnool District 2007-08 & 2018-19

S. No.	Crops in Primary Crop Region	No of Mandals in each Individual Crop Region		Decrease / Increase in the Number of Mandals during 12 Years Period
		2007-2008	2018-2019	
1	Pulses	22	15	-7
2	Ground Nut	13	4	-9
3	Sunflower	10	0	-10
4	Paddy	8	9	1
5	Cotton	-	17	17
6	Millets	-	8	8
7	**Total**	**53**	**53**	-

Fig. 1

Kurnool District Primary crop Regions 2007-2008

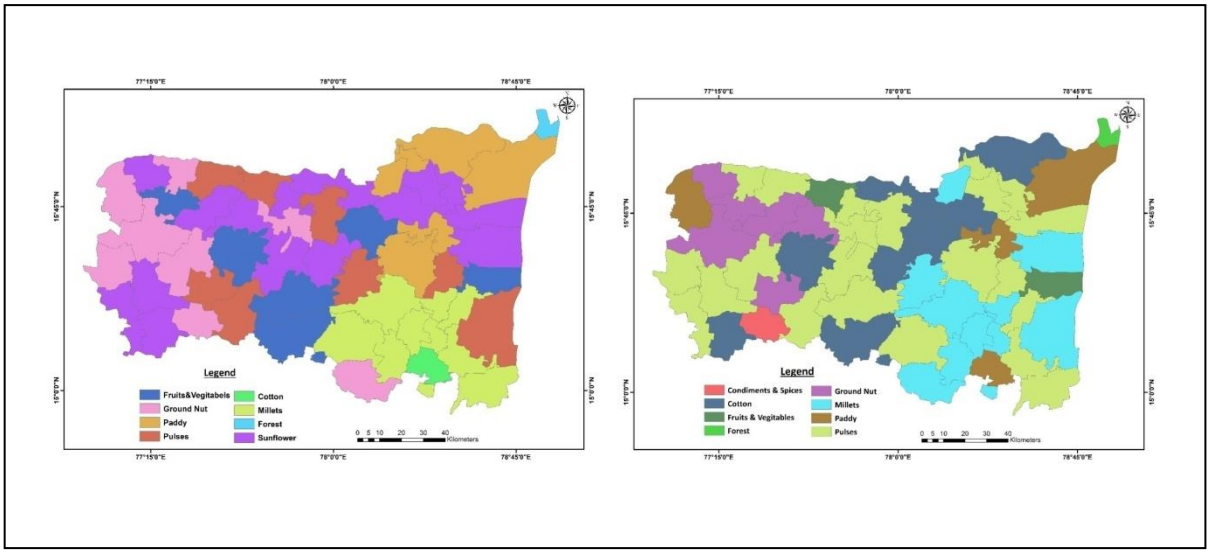
Kurnool District Primary crop Regions 2018-19

SECONDARY CROP REGIONS (2007-08)

Seven crops have been reported in secondary crop regions during the year 2007-08. The maximum number of mandals is in sunflower region found (15 mandals) fallowed by millets region (9 mandals), Pulses (8 mandals), Ground nut (8 mandals), Paddy (6 mandals), Fruits and vegetables (6 mandals) and cotton (1mandal). (Table-2 & Fig. 2)

SECONDARY CROP REGION (2018-19)

During 2018-19, about seven crops gained ground under secondary crop regions. Among these seven crops, Pulses region dominated with 22 mandals fallowed by millets region (10 mandals), cotton (8 mandals), Ground nut (6 mandals), Paddy (4mandals), Fruits and vegetables (2 mandals) and Condiments and spices (1 mandal). Sunflower has lost its place in the secondary crop regions during the study period. Condiments and spices came up as a new crop in the secondary crop region (Table 2 & Fig. 2).



CHANGES IN THE SECONDARY CROP REGION (2007-08 TO 2018-19)

Table -2

Secondary crop regions in Kurnool District 2007-08 & 2018-19

S. No.	Crops in Primary Crop Region	No of Mandals in each Individual Crop Region		Decrease / Increase in the Number of Mandals during 12 Years Period
		2007-2008	2018-2019	
1	Pulses	8	22	14
2	Ground Nut	8	6	-2
3	Sunflower	15	-	-15
4	Paddy	6	4	-2
5	Cotton	1	8	7
6	Millets	9	10	1
7	Fruits & Vegetables	6	2	-4
8	Condiments & Spices	-	1	1
	Total	53	53	-

Fig. 2

Kurnool District secondary crop regions 2007-08

Kurnool District secondary crop regions 2018-19

During 2007-08, seven crops have been recorded under secondary crop regions and the year 2018-19 also seven crops formed secondary crop regions. An increase in the areal spread has been observed in pulses (14 mandals), cotton (7 mandals), Millets (1 mandal) and condiments and spices (1 mandal). Decrease in the number of mandals has been found in fruits and vegetables (4 mandals), Ground nut (2 mandals) and paddy (2 mandals). Sunflower has lost its place in the secondary crop regions. Condiments and spices crop region is the new secondary crop region reported in 2018-19.

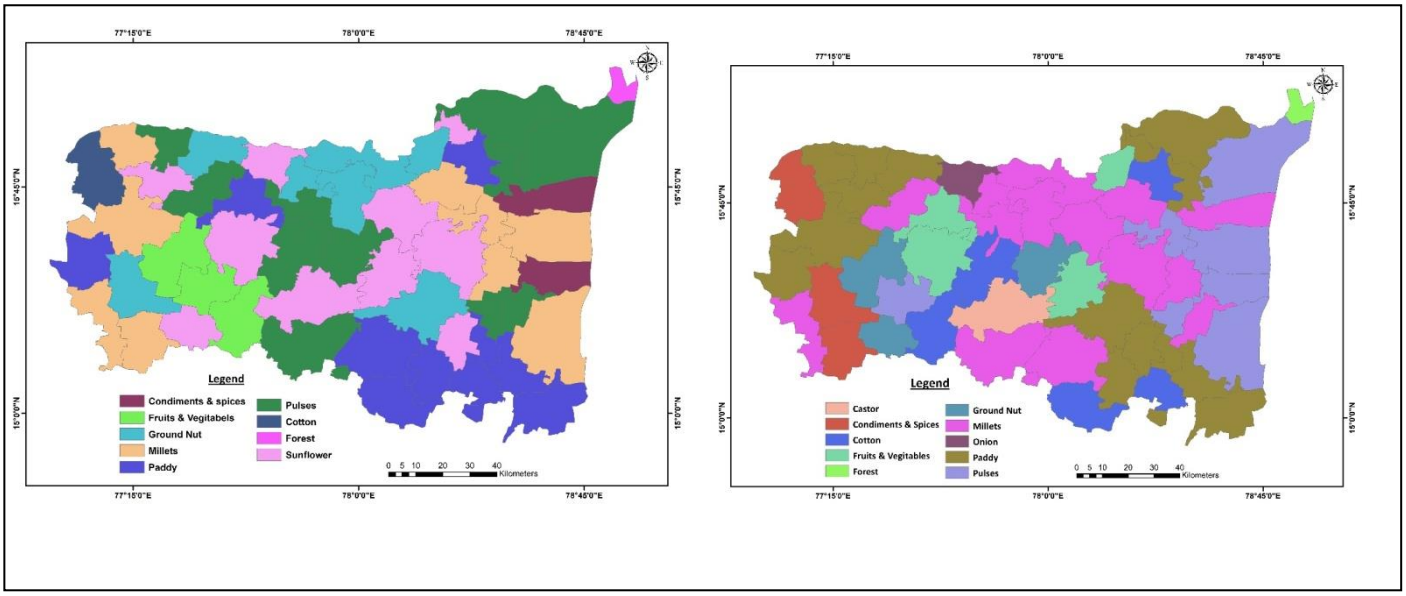
TERTIARY CROP REGIONS (2007-08)

In 2007-08, as many as 8 crops have emerged as the third ranking crops in the district, among which pulses (11 mandals) fallowed by sunflower (10 mandals), paddy (10 mandals), millets (9 mandals), Ground nut (7 mandals), Fruits and vegetables (3 mandals), condiments and spices (2 mandals) and cotton (1 mandal). (Table 3 & Fig. 3).

TERTIARY CROP REGIONS (2018-19)

During the year 2018-19, 9 crops have been noticed under tertiary crop regions with varied intensity. Paddy crop region is emerged as the largest tertiary crop region with 15 mandals fallowed by Millets (14 mandals), pulses (7 mandals), cotton (5 mandals) fruits and vegetables (4mandals), Ground nut (3 mandals), condiments and spices (3mandals), onions (1 mandal) and castor (1 mandals). sunflower has lost its place in the secondary crop regions. Onions and castor crop regions are the new secondary crop regions reported in 2018-19. (Table 3 & Fig. 3)

Table - 3



Tertiary crop regions in Kurnool District 2007-08 & 2018-19

S. No.	Crops In Primary Crop Region	No Of Mandals In Each Individual Crop Region		Decrease /Increase In The Number Of Mandals During 12 Years Period
		2007-2008	**2018-2019**	
1	Pulses	11	7	-4
2	Ground Nut	7	3	-4
3	Sunflower	10	-	-10
4	Paddy	10	15	5
5	Cotton	1	5	4
6	Millets	9	14	5
7	Fruits &Vegitables	3	4	1
8	Condiments &Spices	2	3	1
9	Onions	-	1	1
10	Castor	-	1	1
		53	53	-

Totally about 10 crops have been reported in the study period under tertiary crop regions. They are pulses, Groundnut, sunflower, paddy, cotton, Millets, fruits and vegetables, condiments and spices, Onions and castor. A decrease in the number of mandals each tertiary region during the 12 years is observed in pulses (-4 mandals) and Ground nut (-4 mandals). Increase in the number of mandals under each tertiary crop region during the 12 years of study period is noticed paddy (5mandals), millets (5 mandals) cotton (4 mandals), Fruits and

vegetables (1 mandals) and condiments and spices (1 mandals). Onions and castor crop regions are the new secondary crop regions reported in 2018-19. Sunflower tertiary crop region is absent during the 2018-19.

Fig. 3

Kurnool district Tertiary crop regions 2007-08

CONCLUSION

During the agricultural year 2007-08, Kurnool District in India exhibited four primary crop regions, which included Pulses, Groundnut, Sunflower, and Paddy. However, in the subsequent agricultural year of 2018-19, there was a significant decline in the Sunflower crop region, and it was no longer registered in the district's agricultural landscape. In addition to the existing primary crop regions, Cotton and Millet crop regions emerged previously encompassed within the regions of Sunflower, Groundnut, and Pulses. Regarding the secondary crop regions, the year 2007-08 saw a total of seven crop regions. Unfortunately, in 2018-19, Sunflower lost its place among the secondary crop

regions, and a new crop region, namely Condiments and Spices, emerged, resulting in a total of seven secondary crop Regions.

In both years, 2007-08 and 2018-19, the district reported eight different crop regions at the tertiary level. However, in 2018-19, the Sunflower tertiary crop region was absent, and instead, Castor and Onion regions emerged, replacing one of the tertiary crop regions from 2007-08, namely sunflower. The agricultural landscape of Kurnool District underwent notable changes between 2007-08 and 2018-19. Sunflower experienced a significant decrease and was no longer present in both secondary and tertiary crop regions. Meanwhile, new crop regions like Cotton, Millet, Condiments, and Spices emerged, showcasing the dynamic nature of agriculture in the region over the year.

THE DECCAN GEOGRAPHICAL SOCIETY, INDIA

The Deccan Geographical Society, India established in 1962 at Hyderabad (India) and started publication of Geographical Journal, namely, **"The Deccan Geographer"** since 1962 and **"Bhugol- Shastra Sansodhak"** Journal (Marathi+Hindi and English) since 2006. The journals are devoted to the publication of research papers in the diverse fields of Geography. Papers are invited on any of the themes involving the application of Geographical methodology and the research towards the solution of human problems. It includes papers on recent techniques and currents problems which deal with the issues related to the Environment, Social, Urban, Population and Food Security. The membership of journal is open for geographers, research scholars, planners, decision makers and allied disciplines. The interested persons can enroll for 5 years membership. The membership form is available on DGSI website:

IDENTIFYING THE TRUE COST OF NITRATE CONTAMINATION IN THE MID-GANGETIC PLAIN, BIHAR (INDIA): WHO'S PAYING FOR THOSE COSTS AND WHO'S RECEIVING THE BENEFITS

Narender Singh

Abstract

The Mid-Gangetic Plain (MGP) covers an area of 99,058 km^2 & is a lifeline for millions of people who rely heavily on groundwater. Although this is a region rich in rivers, more than 80% of the irrigation needs of the Bihar plains are met by groundwater, mainly due to easy access, unpredictability and poor irrigation networks. This has led to a rapid decline in water quality and quantity in shallow aquifers. This research aims to understand how nitrate contamination in the groundwater of the MGB has developed over time & comprehend the specific impacts on the rural communities of India particularly those facing socio-economic challenges. Given that a substantial 80% of India's populace resides in these rural regions, understanding & addressing these implications is of paramount importance. The weighted average water quality index (WAWQI) shows that 20.2% of groundwater is unfit for drinking. Surface water irrigation in the 19th century, the introduction of nitrogen-intensive crops (i.e. wheat, rice & sugarcane etc.) & pesticide at higher rate in the 20th century, urban development and groundwater irrigation intensified agricultural activity in the Indo-Gangetic Plain. Furthermore, the districts of South Bihar, compared to North Bihar, naturally receive a disproportionate amount of irrigation water from the Ganga and its tributaries. Additionally, during the non-monsoon season (November to June with little rainfall), groundwater is most often used for irrigation, especially for growing wheat & during the monsoon season (July to October with abundant rainfall), the demand for rice is met by the combination of monsoon rains and groundwater that transfers excess nitrate to shallow aquifers through vertical connections. This can cause secondary reactions in aquifer minerals, leading to the mobilization of toxic pollutants, thereby affecting human health. Other sources of groundwater contamination include unrestricted discharge of partially or untreated sewage and industrial wastewater into surface waters, which eventually percolate underground and contaminate surface aquifers.

Introduction

Nitrate contamination is an escalating concern in India, endangering groundwater safety and public health. Groundwater serves as the primary drinking water source for 85 % of India's rural population and fulfills 60 % of its agricultural water demands. The Ganga alluvial plain hosts a significant population, around 10% of the global populace, with agriculture serving as the primary livelihood in the Mid-Gangetic Plain. (World Bank, 2011) Due to over-exploitation of groundwater for irrigation and instability over time, groundwater levels are currently decreasing, especially in southern Bihar districts (i.e. Buxar, Bhojpur, Rohtas, Kaimur, Aurangabad, Gaya, Arwal, Nawada, Jamui, Banka, Sheikhpura and Lakhisarai). Furthermore, the main factor influencing changes in groundwater storage in the Mid-Gangetic Plain is pumping rather than differences in rainfall. Similar alluvial aquifer systems worldwide have faced water table declines due to unchecked groundwater extraction (Konikow, Kendy et al., 2005; Gautam et al., 2020). Furthermore, the swift pace of urbanization and industrialization poses a major threat, deteriorating both the quantity and quality of groundwater (Nijesh et al., 2021; Pant et al., 2021).

High levels of groundwater nitrate primarily stem from extensive nitrogen fertilizer usage, yet other contributing factors include intrinsic elements like geology, hydrogeology, hydro-geochemistry, biogeochemical processes, as well as external human-driven influences such as land use. These aspects collectively affect the leaching and distribution of nitrate in groundwater. In the last 30 years, northern India has experienced declining water tables due to shifting rainfall patterns and extensive groundwater extraction. While this issue receives considerable attention, the deterioration of groundwater quality from significant pollutants like nitrate, arsenic, heavy metals and organic contaminants is equally concerning, albeit less highlighted. (MacDonald et al., 2016). To solve this problem, the Indian government has proposed to increase the efficiency of groundwater use for irrigation by 20% (MOWR, 2014). A recent study supports this suggestion, showing that different watering methods (sprinkler, drip, and alternating wet/dry systems) can increase efficiency by 23 to 49% without reduces productivity (Bouman et al., 2001) but currently, the impact of this proposed improvement on water levels in the area has not yet been quantitatively assessed. Therefore, consistent and methodical monitoring of groundwater quality is crucial to track contamination factors and develop sustainable aquifer management strategies. (Bonsor et al., 2017). Hence, it's crucial to pay particular attention to shallow groundwater extensively used for household needs.

Objectives

(1) To determine the groundwater quality in the Mid-Gangetic Plain and assessing its adequacy for municipal water supply requirements using the WAWQI (Water Quality Index); and

(2) Moreover, to examine the true costs associated with nitrate pollution in the research region in order to determine which organizations bear these costs and who benefits from this circumstance.

Study Region

The current research area is 99,058 square kilometers, including the latitudes of 24°00′N to 28°40′N and the longitudes of 78°40′E to 86°10′E. It is located in India's Middle Ganga Basin includes 29 districts in the state of Uttar Pradesh. This area is located in an active tectonic zone in the Ganga Plain. The majority of the sediments in this basin are from the Himalayas, which are periodically subject to tectonic movements and climate changes. (Shukla, Raju et al. 2008). Over 30% of India's groundwater supplies are unsuitable for human consumption (Cronin, Prakash et al. 2014). It could be a difficult and nerve-wracking effort to provide drinking water to approximately 700 million rural Indians who live in 15 different ecological regions. Additionally, water-related chronic diseases impact the economy and cost the country approximately 180 million working days annually. (Water Aid, 2007). According to the Agency for Toxic Substances and Disease Registry (ATSDR) of 2011, the toxicity ranking nitrate is 220 but this groundwater contamination challenge impact socioeconomically deprived rural inhabitants in India, where about 80% of the population resides. The concentrations of nitrate in drinking water, primarily induced by agricultural activities, exceeded the Bureau of Indian Standards (BIS) of 45mg/L in 11 states of India. The first reported case of high concentrations of nitrate was in the southern district Rohtas of Bihar. (Ray, et al., 2000) Later, groundwater nitrate contamination greater than the BIS standard was reported in a total of 266 and 503 blocks (out of 534) in 9 districts (out of 38) respectively. (Mishra, Shaw et al. 2009). In the consecutive years numerous habitations were found contaminated with nitrate levels greater than the World Health Organization (WHO) standard of 50mg/L. Elevated levels of nitrate in the soil and in the food chain, and health risks associated with the consumption of nitrate through water and foods were also reported in the state. (Singh, Ghosh et al. 2014)

Database and Methodology

Groundwater samples were collected from across the Gangetic plain during the post-monsoon period of 2015 by the Central Ground Water Board (CGWB). They mainly collected samples from hand pumps that draw water from the aquifer. Various factors influencing the chemical composition of water have been extensively studied worldwide using statistical techniques such as hydro chemical scatter plots, simple linear regression, analytical multivariate trilinear regression, multivariate statistical analysis (MSA), remote sensing and geospatial methods. Multivariate statistical analysis (MSA) was used for sedimentary rock aquifers in Canada to understand hydrogeochemical evolution (Cloutier et al. 2008), similar method for assessing aquifer connectivity and sediment flux in Australia (King et al. 2014). In the Ganga basin, researchers have successfully studied the geochemical processes in aquifer evolution and hydro geochemistry using MSA, various graphs and correlation matrices (Pant et al., 2021; Kumar et al., 2021). Geospatial techniques are valuable for spatial visualization and temporary and have been used worldwide to identify potential groundwater areas, understand seasonal variations in contaminants in different hydro geological environments and more. (Nitesh et al., 2021) Maps created with Adobe Photoshop 7.0 taking into account the ATSDR (2011) toxicity level of the contaminant, based on district-level groundwater pollution data for nitrate, fluoride and any other contaminant which we obtained from the official website of Ministry of Drinking Water and Sanitation, Government of India.

Results and Discussion

In Bihar, out of 532 community blocks, roughly 13% of the blocks had nitrate contamination; no district had 100% nitrate contamination. Of the districts in the state, only 4 had nitrate contamination levels of ≥50%, while eleven were completely free of nitrate pollution. A total of 180 community blocks (out of 532) had only one contaminant, according to several groundwater contamination analyses. That is, nitrate contamination affected 8 neighborhood blocks across 6 districts. There were 13 blocks containing iron and nitrate in 8 districts; 5 blocks containing nitrate and arsenic in 4 districts; and 1 block containing fecal coliform and nitrate in just one district (**Fig. 1**). Thus, it determined that four districts are at the extreme end of the pollution prevention scale, and nine districts are at the high priority level, requiring rapid attention to water management. Most of the districts that border the Ganges River are classified as either high priority areas or extreme areas. Groundwater mitigation strategies and interventions should be given top attention in the

districts of E. Champaran, Samastipur, Vaishali, and Kaimur. The current study examined the following research gaps and insights in light of the findings:

(1) Lack of guidelines for the minimum number of drinking water sources (sampling density) in a community and inaccurate data on the pollutants that are specific to a community's water quality.

(2) The inability to prioritize mitigation plans due to a lack of instruments for decision-making resulted in the failure of water management programs.

(3) The monitoring of water quality and mitigation strategies is increased when sampling density criteria, or the minimum number of samples to be evaluated per square mile, are not followed.

(4) Many water filters were created and tested on a national and regional level in the areas affected by multiple contamination; however, the majority of the time the filters failed.

Magic Limit of Nitrate in Drinking Water

What is the safe limit for nitrate contamination to protect public health? The simple answer is that we do not know and can agree with people, who say that the 10 ppm may not be the right number, and that's a completely different discussion as what is the allowable level of nitrate in our water supply, and should we be looking at just the isolation of nitrate alone or should web looking at nitrate in with other compounds such as uranium, fluoride, arsenic or others around?. Another important thing for people to understand that to go based on that 10-ppm number because that's what's legal. It's important to kind of layout where that number comes from (Blue baby syndrome based) decade's worth of health studies and showing the difference between what is legal and what is safe? So presumably that is a good place to start not trying to debate what the magic number is or what should be legal? We do know there is a growing awareness that nitrate contamination is probably associated with a number of public health conditions at levels much lower than the BIS (Bureau of Indian Standards) ISI 201245mg/LNO3-. Conditions are, namely, Colorectal cancer [from0.87 mg/LNO3-N], Abortion [from5.5 mg/L], Premature babies &/or short-term gestation [from5.5 mg/L], Thyroid cancers [from2.5 mg/L], ladder cancer and Spinal bifida, brain tumors and spinal cord defects of babies. (**Fig.** 2)

The Indian Government was and still been failing to put public health before GDP. This is underscored by a "risk analysis" commissioned by CGWB who are

in an illusion that high levels of nitrate contamination in drinking water does not pose a risk to human health so long as yours green. (Anti-oxidants in the diet should provide adequate protection). In the absence of not too many Indian research studies, it is useful to look to first world countries prepared to spend money on much needed research.

Who is Receiving the Benefits for Nitrate Contamination?

The question of who benefits from purifying the water quickly becomes a delicate question when you consider who benefits from using the nitrates that need to be purified. Obviously, it's the producers/farming community in the area, but it's not just the producers, it's the whole chain that makes money from this grain, whether it's cooperatives, selling seeds or selling chemical ointments. This causes the money chain to spread rapidly. In India, the amount of money paid out by the medical system for nitrogen-related cancers or other water contamination-related health concerns is in the millions of INR, as are the health care costs. Who else stands to gain if we successfully address these issues? The quality healthcare that we provide to the rural population is not just for Bihar, but anything that is designed in this state can be applied to other Indian states as well, where we need to take care of the rural population. You can move to another state. Since the main activity is agriculture, we have developed a system to address these issues. How to effectively care for this population could benefit us and, frankly, other places around the world (**Fig.** 2).

Who is Paying Costs for Nitrate Contamination?

In terms of health impacts, obviously the person who is dealing with the disease, the toxicities that comes with the therapy for it. It also then impacts the rest of their life because even though the person who survived the disease, 75% of them will go on to have long term impacts of the care that they received that will require medical attention for the rest of their life. According to a 2015 research report by Gahlot & Kumar, patient registration data comes from Mahavir Cancer Sansthan Hospital in Patna (Bihar) India, shows that the annual registered new patients from all cancers were 20,746 and 50% of the patients belong to 6 districts (Bhojpur, Saran, Muzaffapur, Samastipur, Vaishali & Patna) which fall in Gangetic belt. The study found that 95% of patients were of low socio-economic status and 54% of patients had never attended school. Furthermore, groundwater contamination, poverty, and disease literacy were identified as key important factors for the high incidence of cervical cancer. Who else pays that cost? The family in many different

ways, first of all, obviously the horror of dealing with a child/person who has cancer or others health issues, but in that bill logistics terms, we know that there are many, many costs that are passed on to the family. Whether that is the idea of can they stay employed because it takes so much time off to care for their child both in land outside of the hospital, travel costs that can be impacted more on rural areas for people have to travel such a great distance. So if we say that water quality is having a hand in diseases like cancer or birth defects, the cost is going on to the family Source: MCS (Mahavir Cancer Sansthan), Registration Data 2015, Patna (Bihar). Besides that; when it comes to discussing contamination or setting regulations or policies, or even just changing the practices. The discussion always comes down to cost benefit, and it's much easier to come up with figures for additional treatment at a water treatment plan to or cost too businesses or farms for prevention measures, but feel like downstream cost of the health impacts, which is always missed out, because it is harder to quantify it spreads across many individuals instead of just impacting one entity with financial records even and those impacts are harder to relate directly back to the water contamination. So try and bridge that gap between what we know academically from research about health risks, and then what we can do to advance policy discussions and paint those fuller fair pictures of the costs overall, because it's not just treatment plant or cost to businesses, cost of farms, there is also health impacts and all of those other peripheral impacts really needs to be taken into account.

Conclusion

India's food security is largely dependent on its groundwater system in the Indo-Gangetic Basin (India), hence the current over exploitation of this groundwater resource is a serious worry. The presence of higher groundwater nitrate concentrations in predominantly agricultural parts of alluvial IGB basin aquifers, is of grave concern to the region's vast groundwater-dependent population. The groundwater in most parts of Bihar is getting increasingly contaminated with either nitrate or other forms of dangerous pollutants, as demonstrated by early inquiry and data analysis. This is not a legacy issue, but a worsening situation. The majority of the districts bordering the Ganges and its tributaries are classified as either extreme or high priority zones. Because the exposed communities are socio-economically deprived, water filters capable of filtering numerous contaminants should be produced and delivered at a discounted rate to the affected communities. Furthermore, we must emphasis the importance of long-term monitoring research, including modelling approaches, to aid in the development of more detailed quantification of groundwater nitrate

problems and appropriate groundwater management policies, not only in Bihar but across India. We all benefit if we can increase their (farmers') efficiency, reduce their input costs, and keep nitrogen out of the water. This escalating pollution trend requires immediate and drastic solutions to prevent further degradation of natural water bodies, particularly in developing countries like India, where water shortages exacerbate the issue. Urgent actions are essential to avert the complete deterioration of these vital water resources.

IMPACT OF TROPICAL CYCLONE DISASTER ON LIVESTOCK RESOURCES OF ODISHA

Dr. Damodar Panda, Dr. Rashmi Rani Anand and Dr. Maya Devi

Abstract

Odisha located on the eastern coast of India is being frequently affected by cyclonic storms. Life and property are generally affected by storms and floods. The economy of the coastal Odisha is agrarian, people grow crops, keep livestock to utilize crop residues as fodder, utilize natural fertilizer in agriculture, and augment family income. Economically and socially weaker sections of the society exclusively depend on livestock for their livelihood. Most of the people in the coastal Odisha live in traditional temporary houses made up of locally available construction materials not resilient to cyclonic storms and floods. They keep the domesticated animals mostly milching animals, drought animals, goat, sheep, pig and poultry birds in temporary houses. As part of the disaster management policy adopted by the state govt. evacuation of population could minimize human casualty, but no such policy adopted for a long time for livestock, which results injury and death of large number of livestock and poultry birds. Realizing the importance of livestock for the rural economy in the disaster-prone area, state govt. has initiated measures for evacuation of livestock and their care during disaster. In spite of this recent measure still large number of livestock and poultry birds are killed due to the impact of cyclonic disasters. The only solution is the construction of permanent livestock sheds in the coastal villages, awareness generation among the livestock farmers, post disaster care and insurance of the livestock.

Introduction

Disasters affect animals and human beings with more impact on animals. Animals are more vulnerable to disasters than human beings. In the developing countries the impact of disasters on animals is higher and more long lasting than in developed countries (Heath et al 1999).In developing countries livestock employs more people than developed countries (Schwabe 1984). In India, 70% of all livestock

are owned by 67% small and marginal farmers, who depend on animal husbandry for their livelihood. The contribution of animal husbandry to the GDP of India has grown up significantly over the years. Disasters that affect animals can, therefore, reduce an important source of employment, revenue and wealth particularly affecting small, marginal farmers and landless livestock keepers who often solely depend on livestock for their livelihood. In spite of serious implications of natural disasters on livestock and livestock owners, disaster management of livestock has yet to receive attention in India as also many other developing countries of the world (Sen and Chander 2003).The Livestock sector plays a central role in nature resource based livelihood of the vast majority of population and often considered as the poor people's ATM. Apart from providing a subsidiary income, rearing of livestock is a source of nutrition in the form of milk, egg and meat. They are kept as a unit of production and provide an important source of revenue, employment and wealth. This sector is facing problem due to the natural disasters like cyclone and flood. Lack of well-developed disaster management plans results in a severe loss of human life, animal life and property, which could be saved if necessary, mechanisms were evolved. The preparedness, response and rehabilitation mechanisms were primarily focused on human beings, whereas, inadequate attention to livestock management led to heavy losses and delayed recovery from livestock related damages. Whenever any region, country or a place is struck by any natural calamity be it cyclone, flood, earthquake, volcanoes etc. the livestock is first to be affected, the reason being the government's relief and rehabilitation measures are focused primarily on population and therefore the sector gets least importance.

Study Region

Odisha is located on the east coast of India with a coast line of 480 km along the Bay of Bengal. The state has an area of 15,5707 sqkm. and consists of 30 districts. Physiographically the state has been divided in to (i)-the northern plateau, (ii)-the central river basin, (iii)-the eastern hills, and (iv)-the coastal plain. The climate is tropical monsoon. The coastal plain of Odisha is agriculturally developed with high population density. The coastal districts are economically developed in comparison to other parts of the state. The state is vulnerable to multiple disasters. Due to its subtropical coastal location, the state is prone to tropical cyclones, floods, tidal surges and tsunamis. The state accounts for 4.05 % population of livestock in the country. According to 2012 livestock census, total livestock was 207.33 lakh Cattle and buffaloes-59.56%, goat and sheep-38.56%, pigs-1.35%.

Objectives

(1) To study the impact of cyclonic disasters on the livestock resources.

(2) To analyze various measures taken by the govt. and the community to reduce the loss and injury of the livestock.

(3) To analyze the livestock affected and loss in the districts.

(4) Suggestion for various measures to be taken to reduce the impact of cyclonic disasters on livestock resources.

Database and Methodology

Data were collected from memorandum on Cyclones from the Special Relief Commissioner, Govt. of Odisha. Disaster management plan of livestock, Animal Resource Development Sector, Govt. of Odisha, Economic survey of Odisha, review of literature, electronic and print media. Data has been analyzed at district level and presented as graphs to understand the trend of cyclonic disasters affecting livestock and loss. Also analyzed the spatial vulnerability of livestock by composite index.

Impact of Cyclone Disaster on livestock Resources of Odisha

Super Cyclone, 1999

The Super Cyclone of 1999 was the most destructive Cyclonic storm of the century. The most severe Super Cyclonic Storm hit the coast of Odisha near Paradeep on 29th October 1999. It affected severely 12 coastal and adjoining districts with wind speed of 270-300kmph and tidal surge of 5-7 m. height. The disaster management policy of the government was rescue and relief operation. The Cyclone prediction was not accurate in its intensity, wind speed, direction and timing. Warning was received three days before the Super Cyclone. People did not take the warning seriously, thus Resulted heavy human and livestock casualty. Lack of adequate cyclone/flood shelters and the shelters constructed by the red cross society was in damaged condition and few in numbers. Numbers measures were taken for evacuation of livestock to safer places before Super Cyclone. The livestock farmers received the warning through various sources well before (24 h to 12 h) the onset of the Super cyclone but, majority of them could not shift their animals to safe places. Non availability of sufficient safe shelters was the most important problem of shifting livestock, non availability of shifting arrangement, delay in decision making and ambiguity of warning. As a result, the majority of the livestock farmers

only untethered their animals before leaving home to save their own lives. They did not put much value to the warning due to their own judgment about the possible impact of the cyclone since they underestimated the impact. The warning messages could not provide information on the possible magnitude of the damage that the cyclone may cause and that might be the reason, why many of them did not think of an early evacuation. Livestock farmers had to suffer a lot for carcass disposal. Since most of the study area remained flooded by the sea water for about a week or more the farmers could not bury or burn the animal bodies. Later, Non-Governmental Organization (NGO) and Amy personnel took the responsibility but it was after 10 to 15 days of the Super Cyclone. The Veterinary personnel were not involved in the carcass disposal as they had no skills and experience. Marginal and small farmers suffered the most due to loss of livestock in the cyclone since they owned large number of livestock. The loss of farmers could have been reduced significantly had insured their animals. The Super cyclone. brought about major decline in the numbers of cattle, buffalo, sheep and ducks, while goat, pig and poultry only made up the loss quickly but also made impressive gains in their numbers by the year 2001(Kurup 2003).It was also reported that the affected areas were the major producer of milk, meat and eggs (Bhanja etal1999) and severe scarcity of milk and milk products were noticed in the coastal districts of Odisha even after 2 years of the Super cyclone(Das 2002).Government paid compensation of Rs.2420.48 lakh for loss of animals and birds, supply of chicks for immediate recovery programme Rs.322.50lakh,establishment of poultry units for the poor families Rs.938.00 lakh, community fodder cultivation Rs.190.00lakh,growing of perennial trees for fodder Rs.186.00lakh and development of fodder nurseries Rs.13.89lakh.Govt spent Rs.4070.871lakh for livestock due to Super Cyclone impact.

Phailin

The very severe cyclonic storm (VSCS) Phailin hit the southern coast of Odisha at Gopalpur on 12th October 2013 with wind speed of 205-220kmph and tidal surge of 3-3.5 m. height ravaged 14 coastal and adjoining districts of the state. On getting the information from the IMD on 8th October, the state govt. intimated to all the collectors, the print and electronic media. On the 10 of October 2013, the IMD reported that the deep depression had intensified in to a Very Severe Cyclonic Storm named as Phailin, indicating the threat to Odisha coast along with the track and intensity of the system. Accordingly, the collectors of the 14 coastal and adjoining cyclone prone districts were alerted through mailman and telephone. As part of the preparedness measures steps were taken for cattle health and supply of cattle feed

for the affected cattle population. Steps were taken to shift 31,062 livestock to safer places.283 veterinary teams were deployed, 89840 livestock treated, 230400 cattle vaccinated, 849.25 MT of cattle feed distributed among 29248 livestock in 1284 cattle camps. They were directed to take all precautionary/preparatory measures to meet the cyclone threat. Total livestock affected were 4689838 with 3250810 Large livestock and 1439028 small livestock. Poultry bird affected were 2368865. Maximum 1995500 livestock and poultry affected in Ganjam district. Total 4502 livestock lost and maximum 3704 livestock lost in Ganjam district.99159 cow sheds were damaged with maximum 65371 damaged in Ganjam district. As per the relief code provision for the replacement of the animals killed due to Phailin subject to ceiling of 1 large milch animal @Rs.16400 or 4 small milch animal @ Rs.1650 or 1 large drought animal @ Rs.15000 or 2 small drought animals @ Rs.10000 per household. For the reparation of the damaged cowshed @Rs1200 paid. Government spent is Rs.3277.15lakh for the livestock affected by Phailin (**Table-**1and 2, **Fig. 1** and 2).

Hudhud

The Very Severe Cyclonic Storm Hudhud crossed close to the Visakhapatnam coast of Andhra Pradesh on 12 the October 2014 with wind speed of 80-100 kmph. and passed through southern Odisha. IMD, Pune disseminated alert of the affected districts of Odisha from 9thOctober on wards. The state govt. circulated the IMD forecast to the Collectors of 16 coastal and adjoining districts likely to be affected, with instructions to remain in full preparedness to meet any eventuality. Collectors of 8 southern districts were cautioned about the flash flood and instructions were issued to start evacuation of livestock and domesticated animals to safer places before the occurrence of the disaster. Advance arrangements were made for the cattle health care and supply of cattle feed in the affected districts. As preventive measure 22 297 animals were shifted to safer place,106 veterinary doctors and 680 para- veterinary teams were deployed,3140 livestock treated,26950 cattle vaccinated and 159 MT of cattle feed distributed. Large areas were inundated in Kendra pada and Puri districts due to storm surge.15 districts affected due to the disaster. Due to its impact 39350 livestock and poultry affected. 670 livestock killed in 4 districts, Gajapati, Koraput, Malkangiri and Rayagada. Maximum 614 livestock killed in Koraput district.670 big animals,198 small animals and 472 poultry birds killed. About 57 cattle sheds damaged. As part of the compensation and related expenditure, the state govt. spent Rs.5.35lakh for the disposal of caracasses, Rs.41.78 lakh for the replacement of livestock, Rs.30.41 lakh for the distribution of

fodder and Rs.85,500 for the reparation of cattle shed. Government spent Rs.78.67 lakh. For the livestock affected by Hudhud.

Titli

The Very Severe Cyclonic Storm Titli crossed the coast near Palasa of Andhra Pradesh, south west of Gopalpur with wind speed of 140-150 kmph. and tidal surge of 1meter on 11th October 2018. The Indian Meteorological Department (IMD) reported on 7th October 2018 about formation of a low-pressure area over south east of Bay of Bengal and adjoining North Adaman Sea. It was predicted that the depression very likely to move towards Odisha during the next 72 hours. After getting the information from the IMD, the state govt. started closely monitoring the situation and intimated all the Collectors, print and electronic media. In the preparedness measures, all Collectors of likely affected districts were instructed for the evacuation of livestock and domestic animals to safer places and to ensure that no cattle should be left tied in kutcha (temporary)house. All cyclone bulletins and warnings shared by the IMD disseminated through DD, AIR, other electronic media for information of the public. 711 MT cattle feed supplied,208462 animal vaccinated,129637 animal treated,158 veterinary team deployed,1798 veterinary camp opened and 48858 carcasses disposed. Livestock were affected in six districts, Cuttack, Gajapati, Ganjam, Puri, Kandhamal and Rayagad. Total 481068 livestock affected with large animal 299795 and small animal 181273.Total poultry affected were 481068.Maximum number of 190349 livestock affected in Ganjam and Gajapati districts of south Odisha. Government spent Rs.623.58lakh.for livestock affected by Titli.

Fani

Extremely Severe Cyclonic Storm Fani crossed the Odisha Coast between Satapada and Puri on 3rd May 2019 with wind speed of 175-185kmph. and tidal surge of 1.5-meter height. On 28th April, IMD Indicated that cyclonic storm Fani moved northwards and would very likely to intensify in to a very severe cyclonic storm. There was also forecast and warnings for Odisha that light to heavy rainfall likely to occur at one or two places in southern Odisha on 2nd May and heavy rainfall from 3rd May over coastal Odisha. Though there was no warning issued by IMD for the Odisha coast, the state government started closely monitoring the situation. On 30th April IMD reported that the Very Severe Cyclonic Storm Fani very likely to cross Odisha coast between Gopalpur and Chandbali to the south of Puri on 3rd May afternoon. Massive preparedness measures were undertaken by

the government soon after receipt of warning from IMD. The districts were alerted based on the probable cyclone track and impact area.14 coastal and adjoining districts were affected due to the impact of Fani. Severely affected districts are Puri, Khurdah, Ganjam, Kendrapara, Cuttack and Jajpur. The cattle population shifted to safer places and cattle feed /fodder arrangement was made. Instructions were issued to field veterinarians to aware dairy farmers and small animal owners to take immediate measures by shifting their animals to safe places to avoid livestock loss.635 animal shelters in school premises and multipurpose cyclone shelters were identified. Over 40,000 large animals like cow, buffalo, bullock etc. were shifted to such shelters.300MT cattle feed stored to meet the requirement. About 80,000 livestock farmers of such districts were made aware about safeguarding of animals and severity of the cyclone through sending of mobile voice messages under mobile advisory programme. Steps were taken for health care services and carcass disposal. Total livestock affected were 3439282,large animal affected were 2443329 and small animal affected were 996053.Poultry bird affected were 5371373.Maximum livestock and poultry affected in Puri, Cuttack and Khurdah districts. Total 6281 livestock lost, maximum loss in Khurdah, Puri and Cuttack districts.119694 cowshed damaged. 2006.5 MT of cattle feed were supplied and steps were taken for the supply of two thousand quintals of green fodder to the severely affected districts. Mobile veterinary units and 115 rapid response teams were used for conducting veterinary camps,4105 animal health camps organized and 5.08 lakh animals treated. Compensation given for the loss of livestock for the replacement of drought/milch animals Rs.950.92lakh,provision of fodder and cattle health care Rs.2432.85 lakh, disposal of carcass RS.437.56 lakh and reparation of cowshed Rs. 2513.574 lakh. Govt. spent Rs6334. 904.lakh for livestock affected by Cyclone Fani.

Bulbul

Very Severe Cyclonic Storm Bulbul crossed Sunderban delta on 9th November 2019 with wind speed of 110-120 kmph. and tidal surge of 0.5-1.0 m. height. On 5th November IMD informed that the depression would very likely to intensify in to a deep depression and cyclonic storm. It would very likely to move towards Odisha-West Bengal coast. Soon after receiving the meteorological warning, the state govt. started closely monitoring the situation. As per the special bulletin of IMD on 7th November the cyclonic storm Bulbul very likely to intensify in to severe cyclonic storm and move towards West Bengal–Bangladesh Coast. Soon after receipt of warning from IMD, the state govt. took all required preparedness

measures to combat the possible situation. It affected 6 coastal and adjoining districts of north Odisha. Due to its impact 31238 livestock affected with 27344 large animal and 3894 small animal. 6125 poultry affected. Only two districts, Bhadrak and Kendrapara livestock were affected and maximum affected in Kendrapara district. Total 19 livestock killed, 1464 cowshed damaged and maximum damage in Kendrapara district. 312 animal health camps at every affected GPs organized. Compensation given for replacement of milch/drought animal of Rs.4.00 lakh, animal health camps Rs15.60 lakh, reparation of cowshed Rs30.74 lank. Govt. spent Rs.50.34lakh for livestock affected.

Amphan

The Extremely Severe Cyclonic Storm Amphan crossed West Bengal coast of Sundarbans on 20th May 2020 with wind speed of 155-165kmph. and tidal surge of 4-5 m height. On 16th May, the IMD informed that the low pressure area would very likely to intensify in to severe cyclonic storm likely to move towards West Bengal Coast during 18th to 19th May 2020. The coastal Odisha would likely to experience light to heavy rainfall from 18th to 20th May.IMD informed that It was associated with high wind speed and heavy rainfall. As part of the preparedness measure, the government alerted the collectors of the 12 coastal and adjoining districts to effectively handle the disaster. Awareness campaign on protection of animal resources from possible cyclone situation was launched in electronic as well as print media. People were advised to shelter the cattle and domestic animals at safe places. They were advised to evacuate their cattle to the ground floor of the Multipurpose Cyclone Selter/Multipurpose Flood Shelter (MCS/MFS) and other suitable buildings in case of necessity. It affected 10 coastal and adjoining districts. Total 1903 livestock affected with 1249 large animal and 654 small animals. 18875 poultry affected. Livestock affected in 6 districts with maximum in Jajpur district.38 livestock killed with maximum in Keonjhar district.393 cowshed damaged. As part of the compensation Rs.8.20 lakh spent for replacement of drought and milch animal and reparation of cow shed Rs.8. 25 lakhs. Government spend Rs.16.45 lakh for livestock affected by Amphan.

Yaas

Very Severe Cyclonic Storm Yaas crossed north Odisha coast south of Balasore with wind speed of 130-140 kmph. and tidal surge of 2-3m.height on 26th May 2021.Indian Meteorological department (IMD) reported on 20th may 2021 that a low pressure area would very likely to form over north Andaman sea and adjacent

east central Bay of Bengal around 22nd May 2021.it would very likely to intensify in to a cyclonic storm and reach Odisha-West Bengal coasts around 26th May morning. Soon after receiving the meteorological warning, the state government started closely monitoring the situation. As part of the preparedness measure IMD weather bulletin and cyclone warnings were disseminated to Collectors, departments and other stake holders at regular intervals. The livestock and domesticated animals of vulnerable area were shifted to safer places. No cattle let tied in kutcha house. People were advised to shelter the cattle and domestic animals at safe places. They were advised to evacuate their cattle to the ground floor of the MCS/MFS and other suitable buildings in case of necessity. Required vaccines, essential medicines were prepositioned at veterinary hospitals/dispensary and 1500 MT of cattle feed was kept ready by OMFED. Due to its impact 11 districts were affected. Total 1358578 livestock affected with 1022361 large animals and 336217 small animals. 1115810 poultry affected. 72 livestock killed.3024 cowshed damaged with maximum damage in Bhadrak District.75 mobile veterinary teams deployed, 37 animal health camps organized, 1617 animals treated and 5100 animals vaccinated. Compensation paid for replacement of milch/ drought animals Rs.16.684 lakh and cattle feed Rs.148.760 lakhs. Government spent Rs.165.444 lakh for livestock affected by Yaas.

Livestock Affected and Loss in Districts

On the basis of the recent past cyclonic disasters affected Odisha from 1999 to 2021, total livestock and poultry affected in the state was 191,64, 505.Livestock affected was 100,01,907 and poultry affected 91,62, 598. Large animal affected were 70,44,888 and small animal 29,57,119. Maximum livestock 46,89,838 affected by Phailin followed by Fani and Yaas. Least affected by Amphan 1903.Maximum poultry 53,71,373 affected by Fani followed by Phailin (Table.1 &**Fig. 1** & 3). The most vulnerable district is Puri with maximum 3618558 livestock affected and lowest vulnerable district is Dhenkanal with 3011 livestock affected. On the basis of the composite index, very high vulnerable districts are Cuttack, Ganjam and Puri, high vulnerable are Bhadrak, Jagatsinghpur, Jajpur, Nayagarh and Kendrapara, medium vulnerable are Balasore, Mayurabhanj Khurdah, Keonjhar and Gajapati low vulnerable are Dhenkanal, Kandhamal and Rayagada. The vulnerability depends on the number of livestock farmers, intensity and track of the cyclone over the state. The vulnerability of the livestock is gradually declining as the people are more aware, construction of more permanent cowsheds and alternate shelters for the livestock during cyclones (**Table-**1 and **Fig. 1** and **Table-**2)

Livestock loss

Loss of livestock and poultry are due to the impact of very high wind speed coupled with flood and damage of temporary structures. Total livestock lost was 456110 with maximum livestock lost due to Super Cyclone 1999 was 621377. Lowest number of livestock lost was 19 by Bulbul. After Super Cyclone of 1999, loss of livestock drastically reduced to maximum 6281 by Fani in 2019.After Super Cyclone loss of livestock reduced to only 16388 from 2013 to 2021 by six cyclonic storms. Maximum livestock lost 110742 in Jagatsinghpur district, the landfall point of Super cyclone and minimum 10 in Rayagada district of southern Odisha. The composite index shows very high loss of livestock in Cuttack, Jagatsinghpur and Kendrapara districts, High loss of livestock in Balasore, Bhadrak, Jajpur, Dhenkanal, Puri and Khurdha districts.

Management of the impact of cyclone disaster on livestock population

The new disaster management plan incorporates provision for evacuation of livestock and provision of fodder, drinking water and medicine. As preventive measures mobile veterinary team deployed, animal health camps organized, affected animals treated and vaccinated. In Super Cyclone of 1999, the number of livestock evacuated is still very low in comparison to the number of livestock in highly vulnerable areas. Evacuated livestock were kept in flood/cyclone shelters and school premises identified by the district administration for the purpose. People are also asked to take the animals to safer places and don't tide them in cowshed. Developed cyclone prediction, early warning and awareness of the people could able to reduce the loss of livestock. Large number of large and small livestock are affected

due to the temporary cowsheds damage by wind and flood water. Loss of livestock is gradually decreasing where as number of livestock affected are increasing. Death of poultry bird is always high due to high wind speed; adequate protection needs to be taken. Post cyclone storm care of the livestock taken including immunization and fodder supply. Community based organizations lacked the necessary trained manpower, resources and know-how to cope with the challenges. In the aftermath of the cyclone, feed and fodder were scarce and consequently many animals starved and the productivity of animals decreased. The various steps to be taken prior, during and after disaster in relation to livestock management includes: Prevention: a) construction of shelter for animals in cyclone and flood prone areas and in case of shifting animals to safer places preference should be given to bullocks, milk cows, breeding bulls as their loss can cause immense damage to economy. b) Untethering the animals when shelter is not available c) Efforts should be made to collect feed, fodder, medicine etc and they should be kept at safer places d) Proper training should be given to farmers for evacuating their animals. Relief: a) Proper care should be taken to protect the animals against prey, poisonous snakes and reptiles b) proper arrangement for quick movement of veterinary personals to reach animals for treatment, vaccination and deworming. Rehabilitation: a) Livestock owners should be provided with compensation in case of livestock loss or diseased condition b) Working bullocks and milch animals should be provided from other unaffected regions that are surplus in these animals c) Reconstruction of veterinary and A.I centers that are damaged due to floods d) A permanent feed security system should be set up in flood prone areas) Livestock owners must insure their livestock. The scarcity of feed and fodder after any disaster poses a serious and indirect threat to the livestock. The use of urea treated straw as a feeding option that has the potential of meeting up the challenge to some extent. The straw feeding during the disasters can reduce the burden on the already scarce feed resources without compromising the production performance and also suggested use of Urea Molasses Mineral Block (UMMB) as a viable feeding option during disasters. Further, by products of sugarcane like bagasse, molasses, sugarcane tops etc., should be fed to animals during scarcity period. They also reported that urea when used for treatment of bagasse enhances its nutritional quality and steam treatment can also be used to increase its digestibility.

Conclusion

Exposure to cyclonic disasters and their consequences play a significant role to the socio-economy of the coastal Odisha. Livestock support the livelihood of

majority of the people of this region. Livestock are the easy victim of the cyclonic disasters as people keep them in highly vulnerable temporary cowshed. Protection of livestock resources should be given top priority for livelihood support of the poor people of the coastal villages. The number of livestock loss has been reduced due to preventive measures taken by the government but adverse impact on livestock is increasing. After disaster fodder problem becomes critical as dodder damaged by flooding water. Steps must be taken for availability of cheap fodder for the livestock. The number of poultry loss is increasing as the birds are sensitive to high wind speed. Number of livestock affected due to temporary cow sheds are increasing though the loss is reducing. Inadequate shelters for the livestock increase vulnerability. Steps must be taken to reduce death of livestock by construction of permanent cowshed. Compensation given for the loss of livestock and poultry ceiling must be removed by fully compensation by alternate agency. All livestock owners must insure their livestock for their benefit. Livestock farmers severely affected by loss of livestock should be provided alternate livelihood support.

SPATIO-TEMPORAL VARIATIONS OF AGRICULTURAL LABOR WAGES IN INDIA

Professor Upma Chaturvedi and Abhinav Singh Yadav

Abstract

The paper analyzed variations in agricultural labors' real wage in 19 states of India from 2005-06 to 2020-21using statistical methods. For a comprehensive study and analysis of the changes in agricultural labour wages across the country, the paper attempted three statistical methods viz comparative analysis of agricultural wages' means across the time period; measuring fluctuations in the change in wages via coefficient of variance; and compound annual growth rate of agricultural wages. Mean real wages of Indian states across the years shows that, Southern and North Western states have higher wages as compared to states in Great Northern Plains, North East India and Central Uplands. Some states have deviated from general trend of increase in wages with the increase in economic growth and development. This decline in wages occurred both in states observing high and low agricultural wages. This anomaly emerged as a national concern because of its spatial diversity across the country and raising frequency in recent years. Fluctuations in the real wages of agricultural labor of different states across the years have no relation with actual real agricultural labor wages of the state. Both states with high and low wage rates experienced high as well as low fluctuations also. Growth rate of agricultural labor wages showed an inverse relationship with the past's real wage rates, that is, states which had high wage rates in past have showed relatively slower growth as compared to those states that had low wage rates. Agricultural labor real wages' increment requires special attention by the policy makers and administrator as it plays major role in boosting rural economy by raising demand of goods and services that too by masses, increasing production process conferring more diverse employment opportunities to disguised unemployed individuals, adding family income and improving standard of living by boosting education and health.

Introduction

A person is treated as an agricultural labor, if he/she follows one or more of the following agricultural occupations in the capacity of a labor on hire, whether paid in cash or kind or partly in cash and partly in kind: farming including cultivation, growing and harvesting of any agricultural commodity; production, cultivation, growing and harvesting of any horticultural commodity; dairy farming; raising of livestock, bee-keeping or poultry farming; and any practice performed on a farm as incidental to or in conjunction with the farm operations (including any forestry or timbering operations and the preparation for market and delivery to storage or to market or to carriage for transportation of farm products). Most deprived section of rural India is landless families who either migrate toward cities or work as agricultural labor. Agricultural workers constitute the most neglected class in Indian rural structure. Agricultural laborer's households constitute the historically deprived social groups, displaced handicraftsmen and dispossessed peasantry. Since, they possess no skill or training, they have no alternative employment opportunities either. Agricultural labors are socially and economically poorest section of the society. They are the poorest of the poor in rural India. The reason for their poverty is their easy exploitation because they remain largely unorganized, therefore their level of income, standard of living and the rate of wages have remained abnormally low. Demand of agricultural labor has declined due to improved farming methods and mechanization of middle and rich farmer's fields, decline in demand and abundance of supply pulled down the wages of the laborers making them economically further more weak. Agriculture laborer wages are function of demand supply of labor, irrigation and cropping intensity of region, fixed minimum wages, price of farm output in the market determining the paying ability of the employer, cost of living etc. Therefore, agriculture laborer wages are different in different states.

Study Region

The study is based over 19 states of the country including Andhra Pradesh, Assam, Bihar, Gujarat, Haryana, Himachal Pradesh, Jammu & Kashmir, Karnataka, Kerala, Madhya Pradesh, Maharashtra, Meghalaya, Odisha, Punjab, Rajasthan, Tamil Nadu, Tripura, Uttar Pradesh, and West Bengal. Data of CPI-AL base year 1986-87 is in continuity and gives data of parent and child state data on the name of the parent state to sustain continuity in the data, For example, Chhattisgarh from Madhya Pradesh, Jharkhand from Bihar, Uttarakhand from Uttar Pradesh, and Telangana from Andhra Pradesh. Therefore, these states are not studied separately rather they are clubbed with the parent states.

Objectives

The objective the paper is to analyze spatio-temporal variation of agriculture labor real wages across different states of India, finding out fluctuations in trend of increase in agricultural wages and evaluating growth rate of increase in agricultural wages in India.

Database and Methodology

Secondary data of nominal wages of agricultural laborers of different states used in the paper is extracted from Labor Bureau Shimla, Ministry of Labor and Employment, Government of India for 2005-06 to 2020-21. Consumer Price Index Agricultural Labor data for the same time period is taken from Handbook of Statistics on Indian States, RBI and Labor Bureau Shimla. State Indices:

$$I_n = \frac{\sum P_n Q_0}{\sum P_0 Q_0}$$

Whereas: I_n= Index Numbers

P_n= Price of current period

P_o = Price of base

Q_o = Quantity of base year

All-India Index: The all-India index is worked out as a weighted average of the indices of 20 States, weights being the estimated consumption expenditure of all rural and agricultural labor households in each State as a proportion of corresponding expenditure for all-India. All-India group indices are also compiled by using the State weights in the particular group, derived as a proportion of corresponding expenditure at all-India level. Base year of CPI is adjusted to 2014-15 for whole data set using following formula:

$$\frac{x}{CPI(214-15)} \times 100$$

x = CPI (2005-06 to 2020-21)

In the study real wages are used instead of nominal wages which is calculated using following formula:

$$Rw = \frac{Nw}{CPI} \times 100$$

Whereas: Rw = Real wage

Nw = Nominal Wage

CPI = Consumer price Index (Agricultural laborers)

Coefficient of Variance is used to measure the fluctuations in the wages of different states. Following formula is used in the study to find out growth rate of agricultural wages along with compound annual growth rate:

$$GR = \frac{PRw \quad CRw}{PRw} \times 100$$

Whereas: GR = Growth Rate

PRw = Previous Year Wages (average of 2005-06 to 2007-08)

CRw = Current Year Wages (average of 2018-19 to 2020-21)

Result and Discussion

Spatio-temporal Variation in Agricultural L labourer Real Wages

Average of 16 years (2005-06 to 2020-21) real agricultural labor real wages in India shows that 8 out of 19 states (Kerala, Jammu and Kashmir, Haryana, Himachal Pradesh, Punjab, Tamil Nadu, Tripura and Rajasthan) showed higher wages than national average with exceptionally high wages in Kerala followed by Jammu and Kashmir while the minimum wages are being paid in Madhya Pradesh followed by Maharashtra, Odisha, and Gujarat. Kerala labors are paid high wages due to high demand and low supply of labors. Kerala labors tends to migrate to foreign countries for grasping better opportunities in the form of high wages, better and safe working conditions facilitated by premigration established linkages. Cost of living in Kerala is also high therefore labor wage is highest among all states. Demand of labors in Jammu and Kashmir is not fulfilled as migrants avoid to migrate there because of volatile law and order conditions along with harsh climate and topography. Thus, leaving only local labors in the market for work that too for shorter period of time allowed by climate for cultivation. Himachal Pradesh is known for out migration. Many villages in Himachal Pradesh had turned into ghost villages because of migration by nearly all families out of their village. This trend of migration by youth causes lack of labors in the state. Demand of labors had increased due to rise in horticulture, evolution of modern technology to practice farming at mountains, and improved marketing facility in the form of better roads, and enhanced communication facility. High demand and low supply of labor made

the agricultural wages of Himachal Pradesh high. Haryana and Punjab are hub of highly intensive agriculture which needs capital, technology and labors in large quantity. States themselves are not capable to fulfilled labor demand therefore in-migration of agricultural labors from low wages states like Uttar Pradesh and Bihar is observed in Punjab and Haryana. Only significantly high wages could attract labors to work far from their local area, thus they are offered higher wages. Along with agriculture, Haryana and Punjab have good level of industrialization which creates parallel demand of semi-skilled and non-skilled labors benefiting labors in the form of high wages at both places. Haryana is bordered with national capital which offers huge employment opportunities in tertiary sector, offering opportunities of wages in agriculture sector. Madhya Pradesh and Odisha have high tribal population that migrate and to labors to shift towards tertiary sector. This again push towards increment work as agricultural labor at a very low cost. Their bargaining power is low and their migration also results into adequate supply of labor in the market. Per capita income of farmers is also very low in these states and farmers practicing commercial agriculture are very less, thus these state experience low wage rates. Odisha is one the major rice producing states of India with limited mechanization of agriculture thus leaving large scope for labors to get engaged. Despite state's large share of rice production very meagre amount is cultivated for commercial purpose and mostly done for domestic or self-consumption which don not allow farmer to hire labor on high wages. Family members themselves cultivate in spite of hiring labor. Maharashtra and Gujarat are also among those states that receive maximum number of in-migrants thus they ensure supply in the market. Maharashtra is the state with very high farmers in distress making the state topper in farmer's suicide. The farmers of the state use minimum inputs for the agricultural production. Labor being a factor of production is avoided by the farmers up to possible limits. Uttar Pradesh and Bihar have huge human resource having low per capita income with suitable geographical conditions for cultivation and irrigation source in the form of rivers, canals and underground water. Bihar lags behind in development of other sectors of economy viz secondary and tertiary, which leaves little room for workers to find employment elsewhere, thus there is excessive supply of labors in the market with demand at fewer location causing fall of their wages. Due to high population in both of the states, agricultural land suffered from fragmentation in large scale, making the land unsuitable for commercial crop and fit only for subsistence agriculture which do not support high agricultural labor wages (**Fig. 1**)

Generally, it has been observed that with the economic growth, wages of employees of every sector (including agriculture) increase, but this is not universally applicable. For example, in Gujarat agricultural real wages had declined in 2017-21 period as compared to 2005-09. In many other states also during same time frame, agricultural real wages have seen decline instead of rise. For example, in Himachal Pradesh, Kerala and West Bengal wages declined in 2009-13 from 2005-09. Andhra Pradesh, Punjab and Tripura have seen higher wages in 2009-13 period as compared to 2013-17. Mean data shows that 7 states have witnessed decline in real wages in 2017- 21 as compared to 2013-17 viz Assam, Haryana, Jammu and Kashmir, Meghalaya, Punjab, Rajasthan and Tamil Nadu. Further analysis used 2017-18 as watershed and taking average of 3 year before and after that time period to find out the recent trend of the change in wages of agricultural labor in the country. Out of 19 states, 11 shows that a declining trend of real agricultural wages. They include Assam, Gujarat, Haryana, Jammu and Kashmir, Kerala, Maharashtra, Meghalaya, Odisha, Punjab, Rajasthan and Tamil Nadu. Although pan India data shows increase in real agricultural wages but that is very minute. State irrespective of the actual wages showed declining trend for example, Kerala, the highest paying state and Gujarat second lowest agricultural wages both showed decline in wages. Most significant decline is showed by Tamil Nadu (5.21%), Meghalaya (11.48%), Jammu and Kashmir (5.06%) and Rajasthan (-6.31%). All the states are located at four corners of the country which indicates that the decline in wages in not a regional issue rather a matter of national concern. Making 2014-15 as the divide line for comparison of previous and current agricultural wage we found that most of the states have improved their agricultural wages except for Gujarat and Tripura. Looking at the comparison of before and after 2014-15 collectively with the average of 2015-16 to 2017-18 and 2018-19 to 2020-21 reveals that the initially wages in most of the states were growing but decline of wages witnessed is a problem originated in very recent times that is after 2017.

Fluctuations in Real Agricultural Wages

Fluctuations in wages means abnormal rise and fall of wages. Fluctuation of wages are unsuitable for agricultural labors' sustained growth in a planned way. High fluctuations in wages demotivates labor to continue with the profession and seeks to engage in another alternative work for stable income. Fluctuation of wages may be caused by natural disaster, interference by administration in wage related issue, MSP hike in any specific crop etc. Coefficient of variance used to find the

fluctuations showed that maximum fluctuation of wages is in Odisha, Maharashtra, Tamil Nadu, and Himachal Pradesh whereas Jammu and Kashmir, Kerala, Gujarat, and Meghalaya are states with minimum fluctuation that is have high stability in wages of agricultural labors. Fluctuations in agricultural wages are independent of the level of wages in the states. States with high wages, shows both high fluctuations and low fluctuations in wages, for example Kerala and Jammu and Kashmir, are low fluctuating states whereas Himachal Pradesh is high fluctuating state. Similarly states with low wage rates also lies in both high and low fluctuating category. For example, Gujarat is low fluctuating state and Odisha is highest wage fluctuating state whereas both have low agricultural wage rates.

Growth Rate of Agricultural Wages in India.

Growth rate of agricultural wages is calculated between 2005-06 and 2020-21 using three years average (2005-06 to 2007-08) as previous data and three years recent data for current entry. Highest growth rate is observed by Odisha followed by Tamil Nadu, Bihar, and Uttar Pradesh whereas lowest is observed by Gujarat followed by Meghalaya, Tripura, and Jammu and Kashmir. These four states have showed negative growth rate, that is the wages in the 2005-06 were more than the 2020-21. This is because of sudden decline in agricultural wages due to economic impact of COVID-19. Despite fall in wages in current year due to COVID-19, 15 showed positive growth rate, indicating the overall growth in the wages. Compound annual growth rate for analysis of successive hike in wages over the years showed that Tripura and Gujarat experienced negative growth rate and very small positive growth rate is experienced by Meghalaya and Jammu and Kashmir. Highest growth rate is experienced by Himachal Pradesh, Odisha, Rajasthan and Bihar. A general trend observed in the growth rate is that states with high wage rate shows slow or negative growth rate for example Jammu and Kashmir and Kerala whereas the states with low wage rate shows high growth rate like Odisha, Bihar and Uttar Pradesh. Coefficient of correlation between compound annual growth rate of agricultural labor real wages and average agricultural real wages of states is negative which again indicates that states having high real wages showed lesser growth whereas as states having low wages rates experienced higher growth rate. This is because development of connectivity, transport and communication technology allowing free and unrestricted movement of labors loaded with required information and knowledge. This eventually is leading towards creating an equilibrium of wages across the country by filling the demand and supply gap.

Conclusion

Agricultural labors are among the most deprived section (economically, socially, politically) of rural society having meagre resources to sustain a meaningful, dignified life. Major and sometimes the only source of their income is the wages they derive by working in fields of others and other related allied activities. Decline in their wage or relatively slow growth as compared to inflation would have harsh impact on their development. Decline in agricultural laborer's wages would lead to reduction in purchasing power and demand of products and services thus slowdown in production process that would again hit the consumption as reduced production would cause increased unemployment, decline in capacity to spend for education, health, skill development. Agricultural labor wages depend upon demand and supply of labors thus in order to increase their wages their supply need to be cut short by engaging them in other sector of economy like decentralized micro, small, medium manufacturing enterprises, food processing industry, providing them with skill training for making them ready for semi-skilled jobs and increasing their demand by promoting farming practices that are more convention, integrated, labor intensive, and natural farming. Community farming or cooperative supported animal husbandry could support their household income and reduce vulnerability. Efforts are needed at central and state policy making level, by demotivating farm mechanization especially at those states that are labor surplus by introduction of seeds and techniques that engulfs more labor and support farmers financially to incur the increased cost of production thus tackling the problem of unemployment, reducing wages of agricultural labors and excessive rural to urban migration in one go.

INCLUSIVE GROWTH: ROLE OF MIGRATION

Dr. Geeta Devi

Abstract

Migration has an intimate association with the development and inclusive growth. While development causes migration the converse is also true. No doubt migration depri ves the society of origin of its young energetic creative manpower, but the remittances sent by them give rise to not only a number of developmental activities but also creates opportunities for all the section of the society in one way or the other. Remittances are most important to development though this depend on a variety of factors as the propensity to remit differs from person to person. Nevertheless, remittances helped in generating employment through the investments made by the migrant households thus helped the migrants and non-migrants equally. Remittances also helped in improving the standard of living of people through enhancing their consumption levels, thus having a multiplier effect on the economy. As the policymakers have shifted the focus away from the quantity of growth to the quality of growth, this paper is an attempt to highlight the key issues regarding the inclusive growth and how migration can impact inclusive growth. Therefore, the main objective of the present research is to know the role of migration in helping for an inclusive growth. To properly understand the relationship between remittance, migration and inclusive growth we need to look beyond household income effects and consider wider social impacts. In the present study the discussion is based on migration and inflow and use of remittances leading to poverty alleviation, migration and inequality, migration and changes in social institutions, and migration and change in role of women.

Introduction

Increasing migration flows in recent decades have been an important element of economic integration at both the global and regional levels, notably in Asia. The main drivers of migration in Asia, as elsewhere, are the wage gap between origin and destination countries, which remains wide, and the lack of employment

opportunities in origin countries, especially less-educated workers. These factors explain much of intra-regional migration by the low-educated (ADBI, 2013). In recent years, many policymakers have shifted their focus away from a narrow concern with GDP growth towards a broader target of 'inclusive growth.' This concept is understood to encompass both a lasting reduction in absolute poverty and a more equitable distribution of the gains from growth (UN, 2010). Since 2011, the Asian Development Bank Institute (ADBI), together with the Organisation for Economic Co-operation and Development (OECD), have organized an annual Roundtable on Labor Migration in Asia as part of its thematic priority in capacity building to promote regional integration and international cooperation and inclusive growth. The main theme of the second Roundtable, held in January 2012, was Managing Migration to Support Inclusive and Sustainable Growth. (ADBI, 2013). During the Roundtable, participating country-of-origin governments expressed the view that outmigration by educated citizens was largely positive. Governments raising this topic expressed confidence that it provides greater returns to education, and these countries hope to benefit from higher per capita remittance levels, the inclusive growth approach takes a longer term perspective. The emphasis on improving the productive capacity of individuals and creating conducive environment for employment, rather than on income redistribution as a means of increasing incomes for excluded groups. Due to this longer term perspective, there is an explicit focus on structural transformation and internal migration in the inclusive growth analytics framework. In developing countries a significant part of growth is generated through reallocation of labor from low productivity to high-productivity sectors.

Objectives

This paper is an attempt to highlight the key issues regarding the inclusive growth and how migration can impact inclusive growth. Therefore the main objective of the present research work is to know how migration weather internal or international work as a key for an inclusive growth.

Database and Methodology

In order to achieve the objectives of the present study, secondary data/ information have been used. The approach adopted for the research work is a systematic literature review strategy. Secondary data was collected from books, reports, journals, research articles having a direct bearing on the subject.

How Migration can help in Impacting an Inclusive Growth

Migration particularly rural to urban migration is one of the most conspicuous processes of the present day. The process can be comprehended in terms of the cause and consequences of migration in relation to the communities of the origin and destination of the migrants. The community structure generates situations which compel the people to make a move on the one hand and, on the other, the process of migration brings about changes in the community structure itself. Migration is a two way process, as it is a cause of development and as well as a consequence of development. The consequences of migration are numerous. These however are difficult to analyze as it involves a number of units and depends also on various factors at the place of origin and place of destination. The rapid growth of cities in the developing world is the major impact of migration. In the 20th century, rural-urban migration was viewed favorably in the economic development literature (Todaro, 1977). Internal migration was thought to be a natural process in which surplus labor was gradually withdrawn from the rural sector to provide needed manpower for urban industrial growth. The process was deemed socially beneficial since human resources were being shifted to locations where their social marginal products were not only positive but also rapidly growing as a result of capital accumulation and technological process. During the growth process, migration has a role to play in bringing about structural changes in the economy.

The consequences of migration are numerous. These however, are difficult to analyze because of the involvement of a number of units such as individuals, families, communities, regions and countries as well as intermediating variables like the socio-economic, political, environmental and cultural background and prevailing conditions at the place of origin and place of destination. Further, quite often, migration has more indirect than direct effects at the places of origin and destination and that too of variable temporal dimensions (U.N., 1984). Impacts of migration depend on the contexts, such as seasonality of movement, educational level of migrants, the length of time spent away, assets and social structures and institutions allowing women and others to pursue activities previously reserved for men and household heads (de Haan, 2000). Therefore to properly understand the relationship between remittance, migration and inclusive growth we need to look beyond household income effects and consider wider social impacts. Migrants impact both the place of origin and destination. And as the links between migration and growth is quite complex as the different aspects of it interacts,

making the quantitative assessments problematic. Therefore, it can observe from the following discussions that how migration impacts economy and society as well leading to an inclusive growth:

Migration and Poverty Reduction

The relationship between migration and poverty is a complex one. Migration can help to reduce poverty and poverty itself is also a cause of migration. But both are deeply interlinked. Researchers on migration have long grappled with the question of whether migration increases or reduces poverty. A consensus has not been achieved partly because of paucity of information and partly because of the tremendous variation across contexts and ethnic groups. The poverty reduction impact depends on a variety of factors like the availability of surplus labour with in the household and village and whether migration increases labour scarcity. Due to a tightening of domestic labor market (both agriculture and non-agriculture); however, that the wage increased in a higher rate in the agricultural sector shows an increase in employment opportunities and alternative particularly for low-income groups. An increase in wage rates can be a pivotal element for rural growth dynamics (Brown et al, 2013; Housen et al, 2012).

A research in Kenya showed even though poor households have less access to opportunities, income from migration may form a more important part of their income than that of the better-off (Knowles and Anker, 1981). Although most international remittances do not flow directly to the poorest people, remittances often make upon important share of the income of the poor people and poor communities as poor people might be affected indirectly through the economy wide effects of remittances expenditure on wages, prices and employment in migrant sending countries (Taylor et. al.1996). Taking the example of Nepal it has been observed that despite the political upheavals, there is a dramatic fall in poverty level and maintaining a stable level of growth over the past two decades, averaging around 4% annually. This sustained growth and reduction in poverty rate is a contribution of outmigration and remittances and this recent growth is termed as an inclusive growth (Maskay and Adhikari, 2013). Teto (2001) estimated that 1.7 million (out of 30 million) Moroccans would fall back into absolute poverty without international remittances and the proportion living below the poverty line would increase from 19 to 23.2 per cent. Another analysis of Egyptian and Ghanian survey data equally indicates that migration enables poor people to move out of poverty. Afsar (2003) also argues that migration has reduced poverty directly and indirectly in Bangladesh as remittances have expanded the area under cultivation and rural labour markets

by making land available for tenancy. Morina, D., Gashi, P. and Morina K., 2015 had observed in their study on Kosovo, that migration is a selective process that affects the growth potential and the welfare of non-migrants as well.

Anh's (2003) conclusions based on data from China, Vietnam, Phillipines and Bangladesh identifies migration as a driver of growth and important route out of poverty with significant positive impacts on people's livelihood and wellbeing. Research by the World Bank and other institutions points to a positive correlation between migration and poverty reduction. A study of 74 low and middle income developing countries reveal that on average a10 per cent increase in the number of international migration in a country's population can lead to a 1.2 per cent decline in poverty (Page and Adams,2004). Therefore, it seems to be of little doubt that migration can reduce poverty and stimulate economic growth (Deshingkar and Gramm, 2004). Migration may have direct and indirect effects on poverty. It can directly reduce poverty by reducing the number of people that a poor household must support. If the potential migrant was not working before leaving, this effect is particularly beneficial. Migration helps stabilize the household income and prevent the household from plunging further into poverty. Migration and migrant can have indirect effects on poverty in the migrant's home community. Migrants leave the local labour force making local labour force more scarce and pressuring the wages upwards, while remittances adds liquidity to local market, potentially stimulating economic activity (de Brauw, 2007).

Migration and Inequality

A commonly held view is that migration increases inequality. The effects of rural out migration on economic welfare in sending areas depends critically on how emigration effects the local capital-labour ratio among non-migrants, that is, on the distributional effects of migration. Moreover, an important concern of the literature on migration is that the poorest are rarely found the major beneficiaries of remittances, at least directly. This is due to the inability to finance expansive moves such as those overseas or those requiring some degree of education. Thus, the impact of migration and remittances on income distribution and in source regions remains a matter of interest in the literature but also of some dispute. The effects of remittances on income distribution and other aspects of wealth is primarily a function of migration selectivity. If migrants mainly originate from relatively wealthy households, migration is more likely to imply greater inequality in the community of origin, while the reverse seems likely if migrants come from relatively poor households, as in the case of Indian rural to urban migration, it has been emphasized

that better off migrants are "pulled" towards better job prospects while the poor are "pushed". "Push" and "pull" migration are twin children of inequality in the same sort of village; but they are also sources of new inequality (Lipton, 1980). It is more correct to say that the impact of migration on income inequality on migrant sending communities vary for different types of migration and for different periods in a community's migration history (see for instance, Stark et.al, 1988). Through the development of social networks between migrants and people staying behind which diminish the risk and costs of migration (Bauer and Zimmermann, 1988), and the flow back of international (Kornar, 1992) less wealthy households initially tend to gain increasingly easy access to international migration. As a consequence of this diffusion process, the initially negative effect of remittances on income inequality might, therefore, be dampened or even reversed in the long term. One might conclude that migration has contributed to increasing household income inequality within a certain community or region however, when comparing this migrant sending region as a whole with other more wealth and centrally located region in the same country (or between countries), one may find that inequality between the region has actually decreased as a consequence of developmental effects of migration (Taylor et. al, 1996). Inequality clearly influences and is in turn, influenced by migration (Waddington, 2003). The search for a better and more secure livelihood drives many migratory movements, and according to Nyberg-Sorensen et. al. (2003), is most common where survival is at stake. Not only does inequality influences who can migrate where, when and how, but it may also be a primary cause of migration. For example, Salemink (2002) shows how internal migration in Vietnam relates to a lack of land rights is customary law for certain excluded social groups. Gaps and access to water and land resource are also documented as causing migration in South Africa (Rwelamira et.al, 2000), Cameroon (Schrider and Knerr, 2000), West Bengal (Ragaly, 2003) and tribal Western India (Mosse et. al, 2002). Here, however the concern is more with how migration influences inequality. Although inequality increasing effects, have been found in various studies at the regional (Adams, 1989) and national (Mishra, 2007) levels, this mechanism is not inevitable.

Migration and changes in Social Institutions

Several historical and empirical studies of immigration have recognized and confirmed that the concentration of particular nationality and ethnic groups in certain cities facilitated the migration of the same groups to these cities (Levy and Wadycki, 1973). Networks play an important role in migration. Kinship ties, friendship and shared community origins are hypothesized to increase migration flows because

they reduce the psychic and risk costs of immigration. These networks connection constitute a valuable social capital that migrants can drop on to gain access to foreign employment and better wages and working conditions (Boyd, 1989).

Massy (1989) has made a case for networks under the assumptions of a risk-diversification model. According to this model families allocate member labour within the constraint of their own needs and aspirations in a cost-efficient and risk minimizing way. Moreover, modernization and development create social and economic dislocations that intensify the unstable and unpredictable economic environment created by the usual risks of drought, crop failure and natural disasters, for rural as well as urban areas. In the absence of other ways to ensure against such risks, diversifications of family members location minimize overall family income risk (Massey, 1989). Networks promote the independence migratory flows for two reasons. First, once network connections reach some threshold level, they amount to an autonomous social structure that supports immigration. This support arises from the reduced social and economic and emotional costs of immigration that network permit. That is, network supported migrants have important help in arranging transportation, finding housing and jobs in their place of destination and in effecting a satisfactory personal and emotional adjustment to what is often a difficult situation of cultural marginality.

These benefits make migration easier, thus encouraging people to migrate who would otherwise have stayed at home unless migrants are uprooted. Education appears to be a major factor in who benefits from and is able to undertake migration with in a community, even if this is only in relative terms (Skeledon, 1997). As stated by the Tilak (2007) also "education is the most critical ele¬ment in empowering people with skills and knowledge and giv¬ing them access to productive employment in the future". Therefore, education is an important sphere of wellbeing that can be affected by migration and a livelihood outcome in its own right. Through migration, individuals may be educated or skilled (i.e. it may be a motive to migrate itself) assuring migration is an accumulated strategy thus future generation may benefit through investment in their education (Waddington, 2003). Expenditure in areas such as education, health, food, medicines and investment in housing as well as community projects for education, health and recreational facilities can enhance people's wellbeing and ability to lead the lives they have reason to value. De Haan (2000) reviews literature from parts of India. Zimbabwe and Kenya finding on balance. That migrants are more educated as education can assist the development of critical consciousness and expose individuals to different values and norms.

Where women are educated they are able to participate in transnational migration and entrepreneurship, sending remittances that help to sustain social networks and participating in migrant organization (Nyberg-Sorenson, 2002).

Work in different parts of India by Parry (2003), De Neve (2003) and de Haan (2003) documents how networks are important even, crucial assets to enable migration. This may be through kinship or other kinds of social affiliation and identities such as caste solidarity. In the former, dependency patronage and other kinds of support (e.g. business partnership) can lead to upward mobility. For the later, the village community can be a good source of information and help with alternatives. In west Bengal, Rogaly (2003) reports how migrants establish long term relations with individual employers, which are crucial for survival. De Haan (2003) reports that caste identity plays a role in the personal networks that mediate migration of migrants to Calcutta. Migration can reinforce the structures, ideologies and support networks for development works and also influence positively institutions such as family, school, social norms and traditions and religious organizations by bringing in new progressive ideas into the development of social institutions and also migrants invest in strengthening these local institutions (Haque, 2006).

Women Migration and Empowerment

The most striking example of the social changes in Nepal resulting from out migration has been the empowerment of women in the rural areas. As men have moved abroad to work, women left behind in Nepal have gained increasing autonomy and discretion over household budgets. In a nationally representative survey of married women, more than half of currently married women who earn cash said that they themselves mainly decide on how their cash earnings are used; two in five indicated that the decision is made jointly with their husbands and only 5% said that the decision is made mainly by their husbands. Similarly, the proportion of surveyed married women who earned cash for their work and who solely decided on the use of their cash earnings has increased from 31% in 2006 to 53% in 2011. It is now recognized that gender equality and female empowerment are central to improvements in standards of living and wellbeing (World Development Report, 2011). Further, the empowerment of women in the rural economy has led to drastic changes such as increasing access to information, offering new choices, and providing demonstration effects. Thus, an unforeseen consequence of foreign labor employment to Nepalese labor is that it has spurred societal changes, namely the empowerment of women in rural areas. It has been argued that female migrants show a deeper commitment than male migrants to providing more economic support to

households that are left behind (Osaki, 1999; Carling, 2005; Boyd, 1989). Several studies indicate that until recently migration was dominated by single men (De Haan, 2000), but things are now changing and feminization of migration is now occurring. In India, regional differences in women's mobility have been noted by Singh (1984 cited in De haan,2000), where migration among women in South India is higher than their northern sisters who live in a cultural milieu that is similar to West Asian and North African Arab countries. Bremen (1996) observed that migrant women in Gujarat, India carrying out equivalent tasks to migrant men earned lower wages. It is sometimes assumed that the migration of men encourages the emancipation of women who stay behind since behind since in their husband's absence, women's responsibilities, autonomy and power would increase (see, for instance, Fadloullah et. al, 2001), while remittances enable these women to assert this newly acquired independence. The pattern in China is still largely male-dominated as a number of studies have established (Zhao, 2001, 2003) both due to cultural reasons restricting female mobility and the nature of the demand for manual workers in urban areas. But more women are migrating to labour intensive industries in areas such as Guangdong. Regional comparisons show that women's migration is very high in South America and South East Asia (Guest, 2003). For example, a study of the cities of Ho Noi and Ho Chi Minh estimates that 40-45 per cent migrants are female (Grace, 2002).

There is micro evidence from several countries in South East Asia that the levels of female migration have increased over recent decades. The employment of women is greatest in the five major export-oriented, labour intensive industries, which are electrical machinary, electronics and computer parts; textiles and readymade garments; frozen and canned foods; precious stones and jewellery and footwears (Clawn,2002). The majority of female rural-urban migrants in East and South East Asia are young and unmarried and the concentration of this group in urban areas is partially in the mega cities (Guest, 2003). This form of migration has increased and become more socially acceptable in South Asia (Siddiqui, 2003). In some areas cultural barriers are breaking down because of the huge opportunities offered by migratory work. Migration thus offers many prospects for helping women to exit from poverty (Deshingkar and Grimm, 2004). It is now recognized that, international migration is positively associated with the status of a women and the opportunities for women to go abroad for employment draws from changes of role of women in areas such as household's decision making, division of labour, gender roles and community perception. Gammage (2004) found that, through migration

and remittances, Haitian women have been able to change the political landscape of Haiti and have challenged traditional gender roles. The so called, "autonomous female migration", has increased because of a greater demand for female labour in certain services and industries and not just as accompanying spouses.

The feminization of migration is one of the principal recent changes of population movement. Today women account for about half of the migrant population (Haque, 2006). Both Courbage (1996) and Fargues (2006) hypothesized that besides factors such as older age of marriage, increased female labour participation and improved education migration from North America to European countries has contributed to the diffusion and adoption of European marriage patterns and small family norms and so has played an accelerating role in the demographic transition. Blue (2004) found that females were positively associated with remittances behaviour among Cuban emigrants. The changes in the family and social norms brought by the female migrants are insignificant and potentially beneficial for the society (Haque, 2006).

Conclusion

Inclusive growth is regarded as the new mantra of development. This paper looks at the approach to the building up of a relationship between inclusive growth and migration and how migration is impacting it. Though many have argued that migration deprives poor countries of its valuable human resources, but studies also have proved that migrants are a potential source of development to their origin as they bring with them the new skills, advanced technology and also potential sources of finance in the form of remittances sent by them. Therefore, it can be concluded that migration does not always lead to brain drain but also to brain gain. Therefore, migration weather internal or international promotes the welfare of the economies and help in bringing an inclusive growth and development directly or indirectly, through the helps provided by the migrants to the area of destination or origin, such as construction of houses and cattle sheds, purchase of land and livestock economy, introduction of new farm technology, education etc. To continue the process of economic growth and social transformation to which remittances are contributing, the economies should foster an economic environment conducive to the productive use of remittances. Therefore, migration weather internal or international promotes the welfare of the economies and help in bringing an inclusive growth and developmental process directly or indirectly. To continue the process of economic growth and social transformation to which remittances are contributing, the economies should foster an economic environment conducive to the productive use of remittances. In particular it should maintain a reasonable level

of economic stability through building consensus among the political parties on minimum common economic agenda for development and growth.

PROSPECTS AND CHALLENGES OF SUSTAINABLE TOURISM IN ANDAMAN AND NICOBAR ISLANDS

Dr. Sukanta Sarkar, Dr. Suman Kalyan Chaudhury and Dr. Saidur Rahman

Abstract

The paper discussed the status, prospects, and challenges of sustainable tourism in Andaman and Nicobar Islands. It has been found that there is huge potentiality of sustainable tourism in the islands. Unexplored geographical features, diversified biodiversity, rich cultural heritage, rich tribal culture, evergreen forests, wild life sanctuaries, and river tributes, are prominent factors for the potential growth of the tourism sector. Travellers can enjoy the village life of the local tribes. The islands have plenty of marine wildlife, and amphibian. Cellular Jail National Memorial, Chatham Saw Mil, Samudrika Naval Museum, Anthropological Museum, Corbyn's Cove, Sound and Light Show are the popular places. But, there are also challenges before the tourism industry. Therefore, government should implement policies for mitigating such challenges.

Introduction

The term tourism was introduced in the 19th century and it is associated with the term "sustainable tourism". Tourism industry is important for any country, because it surge growth and demand of products/services of industries in the country. Tourism has the cultural, and economic phenomenon, where people move from one place to another for multiple purposes. It is the short period or temporally movement from the native place. Duration of the visit may be just one night, or up to one year. It always includes the domestic tourism, inbound tourism, and outbound tourism. Tourism industry is considered as a bigger industry in terms of employment and foreign earnings. It improving the communications among the peoples and solving various social disputes. It has many benefits, such as introduction of new technologies, boost in economic activities, infrastructure development, increase global connectivity, source of foreign exchange earnings, improve nations brand image, improvement of living standards, cultural growth etc. Sustainable tourism involved in development of both the present and future generation. It means movement of people outside own houses and visit various

places without harming the natural environment. Sustainable ecotourism benefits both the visitors and the local peoples. It is useful for swelling conservation and economic growth. Travellers can witness the beauty of the natural environment and also learn about the culture of the ethnic peoples. Ecotourism is natural based activities that increases the interest of people about certain places. Such activities will be economically, ecologically, and socially sustainable and helpful for the wellbeing and conservation of the areas. Local people will be benefited through such tourism without affecting their culture and customs.

Objectives

The main objective of this study is to investigate the prospects of sustainable tourism in Andaman and Nicobar Islands, and to study the challenges before the tourism sector.

Study Region

Andaman and Nicobar Islands is a union territory of India. It contains two island groups, Nicobar Islands, and Andaman Islands. The total land area of the islands is nearly 8,249 km^2. There are 572 islands. Port Blair is the capital of the union territory. It is situated 1,255 km from Kolkata, 1,200 km from Visakhapatnam, and 1,190 km from Chennai. Hindi, and English are the official languages of the islands. (**Fig.** 1)

Database and Methodology

(1) Design and approach: The present study is based on the secondary data. The data has been collected from reports of Andaman and Nicobar Tourism, and India Tourism Statistics. Various journals and books have also been referred in the present study.

(2) Method of analysis: To reveal the growth of tourism industry of Andaman and Nicobar Islands in general and the sustainable perspectives of the industry in particular, different methods of qualitative analysis comprising of tabulation and text analysis were performed.

(3) Hypothesis: Data analyses have been done on the following hypotheses:

H0: There are no impact of corona pandemic on the Tourism Industry in Andaman and Nicobar Islands.

H1: There are impact of corona pandemic on the Tourism Industry in Andaman and Nicobar Islands.

Results and Discussion

Tourism industry in Andaman and Nicobar Islands are increasing due to the beautiful beaches, and adventure sports like sea-walking, and snorkelling. Its tropical rain forest is rich with a diversity of animal life. Kalpong River, Alexandra River, Galathea River, and Dagmar River are the popular rivers. Kalpong river situated in Andaman District, are originated from Saddle Peak. The remaining three rivers situated in Great Nicobar. Hydroelectric dam is constructed on the Kalpong River. The top tourist visited places are Port Blair, Havelock Island, Neil Island, Ross Island, Diglipur, Long Island, Cinque Island, Mayabunder, and Little Andaman. Port Blair is the capital and headquarter of Andaman and Nicobar Islands. It is the gateway for the others incredible islands. Veer Savarkar International Airport is the only airport in the islands. It is well connected with the mainland by air from Visakhapatnam, Chennai, and Kolkata. Cellular Jail National Memorial, Chatham Saw Mil, Samudrika Naval Museum, Anthropological Museum, Corbyn's Cove, Sound and Light Show are the popular places of the city. Cellular Jail is a British colonial prison. Today it is a national memorial monument. Wandoor Beach is situated 25 km south-west of Port Blair. It is located near the Mahatma Gandhi Marine National Park. There are plenty of marine wildlife, and amphibian. Saltwater crocodiles are often found on the coasts. Wandoor is also recognized for its Mangroov forest, lagoons, and backwater. Travellers can enjoy the village life of the local people. Agriculture crops (coconut, and paddy) and fishing are the main sources of income of villagers. Travellers can see the rural life of the diversified tribes. It will enhance the rural tourism in the islands.

Table-1 discussed the populations and areas in Andaman and Nicobar Islands. It has been found that south Andaman district have the largest number of population, followed by the North. and Middle Andaman districts. It is the largest district followed by the South Andaman district. Mahatma Gandhi Marine National Park was established in 24th May 1983 under the Wildlife Protection Act of 1972 for the protection of nesting sea turtles, and corals. Twin Islands and Labyrinth Islands are the two major island groups in the park. Majority of the coral reefs are fringing reefs. There are nearly some 20 islands and rocks in the park. Many islands are covered with thick mangrove vegetation, sheet rocks, uprooted trees, and sand covered beaches. There is scope of ecotourism in Red Skin and Jolly Buoy islands. Havelock island is a popular eco-tourism spot. Water sports like as scuba diving, banana boat ride, and sea walking are popular among the tourist.

Elephant beach, Kala Patthar beach, and Radhanagar beach are the popular beaches. Tourist can also enjoy the mangrove safari, fishing, trekking, scuba diving etc. Neil Island is situated 40 Km. away from Port Blair. Sitapur beach, Laxmanpur beach, and Bharatpur beach are popular beaches of Neil Island. Travellers can witnessing the unexplored coral reefs. Ross Island is an uninhabited island. The ruins and a small museum of Indian Navy is the main attraction of the island. Ross Island is located three km. east from central Port Blair. There are many lighthouse towers. Peacocks and spotted deer are easily available in the island. Palm and coconut trees are the native trees of the island. Travellers can see the amazing landscapes and sunset views in the evening. (**Table-**1 and 2)

Table-1: The Populations and Areas in Andaman and Nicobar Islands

District	Capital	Population (2001)	Population (2011)	Area (km.)
South Andaman	Port Blair	208,471	238,142	2,640
N. and M. Andaman	Mayabunder	105,613	105,597	3,536
Nicobar	Car Nicobar	42,068	36,842	1,765
Totals		356,152	380,581	7,950

Table-2: Historical Population Growth in Andaman and Nicobar Islands

Year	Population	Growth	Year	Population	Growth
1901	24,649	-	1961	63,548	+105.2%
1911	26,459	+7.3%	1971	115,133	+81.2%
1921	27,086	+2.4%	1981	188,741	+63.9%
1931	29,463	+8.8%	1991	280,661	+48.7%
1941	33,768	+14.6%	2001	356,152	+26.9%
1951	30,971	−8.3%	2011	380,581	+6.9%

Source: Census of India.

Table-2 discussed the historical population growth in Andaman and Nicobar Islands. It has been found that except 1041-1951 period, in other periods population was increased. Viper Island lies four kilometres west of Port Blair. It is popular among the tourist because for its mesmeric picnic spots, and having historical

importance. Nali, Mud Spitting Volcano, and Kalipur beach are the popular places of the island. Saddle Peak National Park, Orange gardens, paddy fields, Saddle Peak, and expansive greenery and marine life are other tourist attractions. Trekking, scuba diving, and snorkeling are the common activities. Long island has the beautiful eco-huts headed by Blue Planet. Merk Bay, and Lalaji Bay are the popular sports. Clinque Island is a human inhabited island. Tourist can enjoy the wildlife, greenery, and marine life of the island. The Mahatma Gandhi Marine National Park, salt water crocodile, starfish, sea weeds, varieties of coral reefs, fishes, shells, turtles, and sprawling marine life are the major tourist attractions. Mayabunder situated in middle Andamans. It is cultural hub of 71 villages where majority of people are immigrated from Pakistan and Bangladesh. Karmatang beach, and Karmatang Beach have the turtle nesting spots. Little Andaman is paradise for the natural lovers. Travellers can involve in coral watching, fishing, diving, snorkeling, surfing etc. Beautiful beaches, Red Oil Palm Plantation, evergreen rain forests, and waterfalls adds additional satisfactions to the tourist. (**Table-**3)

Source: India Tourism Statistics.

The above **Table-**3 discussed the arrivals of tourist in Andaman and Nicobar Islands. It has been found that number of tourist are increasing continuously since 2010, but declined in 2020, due to the corona pandemic. Domestic tourist arrival was more than 50 thousand in 2019, but it was dropped to only 126238 in 2021. On the other hand, foreign tourist arrivals were 16206 in 2019, and it was just 1687 in 2021. Lockdowns, and travelling restriction due to the corona pandemic is main factors behind the sudden drop of the tourist arrivals. Therefore, the null hypothesis is rejected and alternative hypothesis is accepted, i.e. there is impact of corona pandemic on the Tourism Industry in Andaman and Nicobar Islands. There are three districts in Andaman and Nicobar Islands. They are Nicobar, South Andaman, and North and Middle Andaman. Malacca is the capital of Nicobar district. It is situated in Car Nicobar tehsil. Car Nicobar is located in the northernmost of Nicobar Islands. It is popular for the silvery beach. It is flat island with clusters of coconut palms, and areca nut. It is a small island (only 126.9 km^2). There are 21 villages. It has tropical monsoon climate. Bird watching is popular among the tourist. Green imperial pigeons, Andaman boobooks, White-headed starlings, Andaman cuckoo-doves, Andaman wood pigeons, and Nicobar serpent-eagles are the prominent birds. Car Nicobar is 260 kilometers, far away from Port Blair.

Ship service is available between the two towns, and travellers can collect ticket from the office of the Director, Shipping services, Port Blair. Indian Air Force operating the charter services between Car Nicobar Air Force Base, and Port Blair's Veer Savarkar International Airport, Campbell Bay. Regular service of Pawan Hans helicopter is also available. Mount Thullier is the highest point of Nicobar Island. It is 642 meter above the sea level. Dak Tayal, Dak Aniang, Amrit Kaur, Jubilee, and Galathea are the popular rivers of the island originated from Mount Thullier. Among the rivers, Galathea River is the longest river. Indian passport holders can travel the island, but the foreign passport holder's needs Landing Permits from the Office of the Deputy Commissioner, Andaman District. Indira Point is the most southern point of Great Nicobar Island. Great Nicobar Island is declared as World Network of Biosphere Reserves by the UNESCO. The island is comprising three distinct groups- Northern Group, Central Group, and Southern Group. Nicobarese, Shompen, and Mainland Indians are the ethnic tribes. Galathea National Park, and Campbell Bay National Park of Great Nicobar are protected areas. The island has the tropical climate. Mayabunder is the headquarter of North -Middle Andaman district. It is connected with Port Blair by the Andaman Trunk Road. It is the major highway. This highway connected Diglipur and Port Blair, via Mayabunder,

Nimbudera, Billy Ground, Rangat, Kadamtala, Baratang, and Ferrargunj. The distance between the two places are 242 km. Ferry service also available between them. It is a waystation for several tourist attractions, like as Karamatang Beach (13 km), beach at Aves Island (30 minutes by boat), and mangrove lined tidal creeks. Majority of the population of union territory lives in this district. Port Blair is the headquarter of South Andaman district. It is also the capital of Union territory. It is connected with the main land of the country by sea, and air. Other towns are Garacharma, Prothrapur, and Bambooflat. Bambooflat is located nearly 13 Kilometers from Port Blair. (**Table-**4)

Table-4: District-wise Popular Tourist Places in Andaman and Nicobar Islands.

District	Popular Tourist Places
South Andaman	Jolly Bouy, Swaraj Dweep (Radha Nagar Beach), Netaji Subhash Chandra Bose Island, Chatham Island, Cinque Island, Corbyn's Cove Beach, Cellular Jail, Mount Harriet, Gandhi Park, and Shaheed Dweep.
North- Middle Andaman	Lamiya Bay Beach, Karmatang Beach, Ramnagar Beach, Mud Volcano at Shyam nagar, Kalpong Hydro Electricity, Limestone Caves in Diglipur, Twin Islands - Ross & Smith Islands, Saddle Peak, Kalipur Beach and Turtle Nesting Ground.
Nicobar	Little Nicobar, Great Nicobar, and Car Nicobar.

Source: Official website of the districts.

Table-4 exhibits the popular tourist places in districts of Andaman and Nicobar Islands. It has been found that tourist places are scattered in the districts. Lamiya bay beach is situated in the foothill of Saddle Peak. It is near the Kalipur beach. Karmatang beach is perfect place for the snorkelling and scuba diving. Travellers can observe the olive ridley turtles, hawksbill turtles, green ocean turtles, and leatherback turtle. Ramnagar beach located 35 kilometers from Diglipu. It is more suitable for suitable for swimming. turtle nest is easily available. The beach has the eco-friendly beach facilities, like as seating arrangements, and eco-huts. Mud Volcano located near Hathilevel. The chain of Mud volcanoes can observe in the green jungle of Shyamnagar. Seating facilities along with information boards are available for the tourists. Kalpong dam is constructed on the across Kalpong river at Nabagram. It is only dam in the Union Territory. Turtle Nesting takes place at

Ramanagar beach and Kalipur beach are popular among the tourist. It is the home to thousands of turtles during their nesting period. Alfred caves is located near the Ramnagar beach. Ross & Smith islands are popular among the tourists. There is a marine sanctuary. It is enclosed by tropical forests. It is the perfect place of trekking and trail hiking. Diglipur is popular for eco-friendly tourists. It is a beautiful place having the orange garden paddy field, forest, and marine life. Andaman and Nicobar Islands are enriched in culture & heritage. Folklore is narrated and folk songs are the part of the festivals. There are many indigenous peoples in the islands. Andamanese are a listed as scheduled tribe as per India's constitution. Traditionally they lived a hunter-gatherer lifestyle, Great Andamanese and Jarawas are the major tribes. Jarawasve lives in Middle and South Andaman Islands. According 2011 Indian census, their population is 380. They are hesitated interaction with outsiders. Tourism department of the Andaman and Nicobar administration issued warning for attempting photographing them, or contact with Jarawas. They are protected under the under the Protection of Aboriginal Tribes Regulation, 1956. Onge is the another tribe. They live in Little Andaman. Their belief system is a form of animism. They are still maintaining their cultural and biological identity. Their population is declining due to their food habits brought about by their contact with the outside world. Therefore, there are huge potentiality of sustainable tourism in the islands. Unexplored geographical features, diversified biodiversity, rich cultural heritage, rich tribal culture, evergreen forests, wild life sanctuaries, and river tributes, are prominent factor for the potential growth of the tourism sector. But, there are also challenges before the tourism industry. Lack of media coverage, ethnic conflicts, lack of alternatives means of transport, boundary issues, poor connectivity, and abysmal infrastructure are the major challenges before the sector.

Conclusion

There is enormous potentiality of sustainable tourism in Andaman and Nicobar Islands. Port Blair is the capital, and the largest city. It is well connected with mainland by air and sea. Cellular Jail National Memorial, Chatham Saw Mil, Anthropological Museum, Corbyn's Cove, Sound and Light Show are the popular places of the city. The top tourist visited places in the islands are Port Blair, Havelock Island, Neil Island, Ross Island, Diglipur, Long Island, Cinque island, Mayabunder, and Little Andaman. Havelock island is a popular eco-tourism spot. Water sports like as scuba diving, banana boat ride, and sea walking are popular among the tourist. Elephant beach, Kala Patthar beach, and Radhanagar beach are the popular beaches. Diglipur is popular among the tourist because for its mesmeric picnic

spots, and historical importance. It is a beautiful place having the orange garden paddy field, forest, and marine life. Travellers can observe the olive ridley turtles, hawksbill turtles, green ocean turtles, and leatherback turtle. Great Nicobar Island is declared as World Network of Biosphere Reserves by the UNESCO. Andaman and Nicobar Islands are enriched in culture & heritage. There are many indigenous peoples in the islands. So, there are huge potentiality of sustainable tourism in the Union-Territory. But certain factors, like as ethnic conflicts, poor connectivity, lack of media coverage, lack of alternatives means of transport, boundary issues, and abysmal infrastructure are the major challenges before the sector.

HISTOGENESIS AND GROWTH OF PATNA METROPOLITAN CITY

Dr. Anjani Kumar and Professor Ram Sakal Yadava

Abstract

"Every place is a history of a life" (Tuan, 1977). Studying the histogenesis and growth of a historical city is not merely an exercise in understanding the past but it is an exploration of the transformative power of human civilization in crafting the urban environment as well. Examination of historical evolution of a city "illuminates the hidden relationships between power and space, revealing a deeply rooted interplay of social and spatial transformations" (Soja, 2010). This research paper delves into the histogenesis and growth of Patna settlement, a city of profound historical significance in India. Through an in-depth examination of historical records, maps and demographic data, this study traces the city's growth, from its ancient origin as Patliputra to its current status as a bustling metropolitan area. The research scrutinizes spatial expansion, population dynamics and key socio-political events that have shaped Patna's trajectory over millennia. The study reveals the pivotal role of strategic location along the Ganga river (Prasad, 2008), successive dynasties (Thapar, 2013) and colonial influence (Rai, 2010) in shaping the Patna's urban landscape. The analysis further delves into post-independence challenges, including economic decline and administrative restructuring, particularly following the separation of Jharkhand from Bihar in 2000. Despite these challenges, Patna's resilience is evident in its population growth which has multiplied tenfold since the early 20th century. This study projects a population of over 4 million by 2051, underlining the city's continued vitality and potential for further expansion. This comprehensive historical account contributes to a better understanding of the city's urban development processes and provides a foundation for urban planning and development in the future.

Introduction

To ensure a better future, it is vital to learn from the past. In order to comprehend the processes and patterns of urban development, it is essential to study the origin, evolution, and growth of cities. An examination of the histogenesis of a city is

necessary to properly comprehend the process of urbanization. The origin of ancient cities is often linked to myths, legends and divine interventions. The discipline of urban geography is concerned with the precise study of a city's location, site and situation in a temporal context. Recent advancements in underground exploration surveying technology have provided a gateway to search for 'city seeds' (Bosker, 2022). The development of cities is intricately tied to the progress of humanity and civilization. While traces of human civilization have been found worldwide, the civilization of the Indian sub-continent has an antecedence of urban nature. The Harappan civilization provides evidence of urban infrastructure such as proper drains, planned housing, lanes, and roads. Furthermore, several cities in mainland India are assumed to have divine origins dating back thousands of years, including Varanasi, Mathura, and Dwarika. Patna city has a history dating back to the 6th century BCE or even earlier. Apart from the Kumhrar excavation, there is no significant evidence of infrastructural traces to date. Historical and religious texts have always made appropriate mentions of Patna's expansion up to the pre-historical Mahabharat period. The travel accounts of foreigners during the ancient period also mention Patna under different names such as Pataliputra, Palibotra (Greek), and so on. The city has been given many names during the rule of different dynasties in the ancient history of the Indian sub-continent. As with other ancient cities, Patna's origin has evinced conflicting claims.

Study Region

Patna, the capital of Bihar, holds a prominent place in the historical and geographical landscape of India. This city, located in the west-central region of the Bihar state, lies in the midst of the fertile Ganga plain. The city falls within the coordinates of latitude 25°30' to 25°40' North and longitude 85°0' to 85°15' East. The city is surrounded on three sides by the Ganga, Sone, and Punpun rivers, and it boasts a unique convergence of four rivers with the Gandak river to the north. The Ganga's southern embankment forms the city's northern boundary, while the Punpun river flows approximately 5 kilometres to the south and the Son river more than 10 kilometres to the west. The city's elevation, averaging 55 meters above mean sea level, encounters lower areas to the southeast that are susceptible to prolonged waterlogging after floods. Most of the metropolitan area is part of the older floodplain, with the western region along the Ganga's embankment classified as an active floodplain. The city's population grew substantially between 1991 and 2011 with a significant "floating" population commuting daily. As of the 2011 census, Patna is home to a population of 2,046,652. The city extends for

about 24 kilometres from east to west, with an average width of 2.5 kilometres and encompasses an area of approximately 142 square kilometres.

Objective

The main objective of this study is to reveal the origin and evolution of the city including its evaluation of its spatial and demographic growth.

Database and Methodology

The study is solely based on secondary sources of data as it delves in to histogenesis and growth of the city. Accessible literature, historical maps, Survey of India Topo-sheets, Census data and other related government reports have been used as secondary data. ArcMap 10.8 has been used to prepare different relevant thematic maps such as extent of urban growth and settlement of urban landscape. MS Excel has been used for data analysis, presentation and interpretation.

Origin

The ancient origins of Patna are steeped in legend, with a multitude of stories surrounding the city's name and foundation. Over the course of its long and illustrious history, Patna has gone by a variety of monikers, from Patligram - a small village named after the patli flower that still grows in the city to this day - to pushpapuri and kusumpura, both of which mean 'city of flowers' and evoke an image of a tranquil city surrounded by blooming gardens. Patliputra is perhaps mostly well-known of these names, a testament to the city's rich cultural and historical heritage as the site of the ancient kingdom of Magadha and the Mauryan empire's flourishing capital. By the time of Sher Shah Suri in the 16th century, Patliputra had evolved into Patna, a name that phonetically resembled the Sanskrit word for 'port', paatan. However, the city underwent another name change when it became known as Azimabad during the Mughal era, named after the Mughal prince Azim-uh-shan, who established a court here. With the fall of the Mughal empire, the people of the city returned to calling it Patna, a name that has endured to this day and is synonymous with images of grand empires, scientific advancement and a rich cultural legacy that remains an integral part of India's history.

Tales and Anecdotes

The narrative from an ancient Hindi manuscript, translated from the Sanskrit Brihatkatha, provides a captivating account of the foundation of Patna. It chronicles the journey of a Brahmin Bhumideva and his sons, Kusa and Bikusa,

along with their wives Pramati and Sumati, who sought their fortune overseas. The intervention of deities Mahadeva and Parvati, prophesizing the birth of a child named Putra with a unique ability to generate a thousand gold coins. Putra, in a gesture of love and identity, established and named Pataliputra after his wife and himself. Following his reign, son Kusuma ascended to the throne, and under his rule, the city was renamed Kusumapur. This narrative intertwines folklore, divine intervention, and urban genesis, offering a rich tapestry of Patna's origin.

Evolution

The city of Patna owes much of its prominence to its strategic location, situated as it is amidst the rivers Ganga, Son, Gandhak, and Punpun. This unique position didn't only ensure its political pre-eminence but also allowed the city to thrive as a hub for riverine trade. Over the centuries, Patna has served as the capital of various powerful dynasties, from the Shishunaga and Nanda to the Maurya, Shunga, Kushana, and Gupta. Each of these dynasties has contributed to the city's cultural and historical heritage, leaving an indelible imprint on its identity. The city has also attracted travellers who found Patna inspiring and wrote vividly about its vibrant personality and historical journey. Patna played a critical role in India's struggle for independence, further cementing its place in the annals of Indian history.

Ancient Period (5th Century BCE to 12th Century CE)

In the 5th century BCE, Ajatashatru of the Haryanka dynasty of Magadh, son of Bimbisara, emerged as a significant ruling figure in Indian history. He was a contemporary of the great souls namely Mahavir and Gautam Buddha. Despite a tumultuous ascent to power, in which he forcefully overtook the kingdom from his father and imprisoned him, Ajatashatru emerged as a successful conqueror. By capturing Vaishali, fortifying a village to form the city of Patliputra, and capturing Kashi and other smaller kingdoms, Ajatashatru secured his position as the ruler of the most powerful kingdom in North India. Between 491 and 961 BCE, Ajatashatru moved the capital of Magadha kingdom from Rajgriha to Patliputra, and his son Udayabhadra succeeded him, leading to the city's growth into the largest city in the region. Although Gautam Buddha visited Patliputra during the last years of his life and prophesied a successful future, he also predicted the city's ruin from Flood, Fire and Feud. In the 4th century BCE, Chandragupta captured Patliputra and established the Mauryan dynasty, which lasted from 321 to 185 BCE. With the rise of the Mauryan dynasty, Patliputra became the centre of power. The city was constructed using wooden structures during this time, with multi-story buildings

and palaces surrounded by ponds and parks. The drainage system was another notable feature of Patliputra. The streets' water route drained into a moat , which functioned as both a defence system and drainage system. In 303 BCE, Greek ambassador Megasthenes visited the royal court of Chandragupta and described Patliputra as an important and fortified city with wooden walls, crowned with 517 towers and 64 gates, all surrounded by a protective ditch. The main gate of the city was protected by a special armed contingent under the kiledar . Megasthenes noted that visitors had to show their identity to the gatekeeper while entering the city. He described Patliputra as a splendid city and compared it to the contemporary Persian sites (Waddell, 1903). In the 3rd century BCE, King Ashoka, the grandson of Chandragupta, extended the Mauryan empire as far as Madras and renovated the wooden capital into a stone construction in 273 BCE. During this time, education and learning received immense state support, leading to Patliputra becoming home to several eminent world-class scholars, including Aryabhata, Ashvaghosha, Chanakya or Kautilya and Vatsyayana. Patliputra was considered the largest city during 300-195 BCE.

Emperor Ashoka's reign marked a significant period of cultural, social, and religious transformation, with his emphasis on Buddhism and his rock and pillar edicts promoting social justice, religious harmony, and non-violence. In 232 BCE, the Mauryan dynasty came to an end with the death of king Ashoka, and the Shungas took control over the kingdom. India then reverted to a group of unfederated kingdoms with the Shungas controlling most of the core territories of Magadha. In the 2nd century BCE, Magadh entered a period of political decline. Although most of the powerful kingdoms were located in the south and west, the north remained culturally active, with Buddhism spreading throughout the region. During the 4th century CE, Patliputra regained prominence under the Gupta dynasty, especially during the reign of Chandragupta I (320-335). He revitalized Magadh by conquering the territory, setting up Patna as the capital and consolidating a kingdom in the eastern region of northern India. Chandragupta I revived some of the principles of king Ashoka's government. However, it was his grandson, Chandragupta II (376-415), who established a vast empire in the north and western Deccan. In the 5th century CE during the reign of Chandragupta II, the Chinese pilgrim Fa Hein visited Patliputra (Po-lien-fu) and recorded the flourishing state of Magadh, as well as the impressive architecture of the city, describing the walls, gates, palaces, and buildings as being constructed in a manner that could not have been accomplished by human hands (**Fig.** 1 and **Fig.** 2). The wooden outer wall that Megasthenes

previously mentioned was still standing in the early 5th century. Patliputra was also home to many stone buildings and a great palace erected by Chandragupta's grandson, Ashok, who had converted to Buddhism. Hiuen Tsang, who travelled through the silk route, visited Patliputra in 1637 CE and found it to be a deserted and crumbling land, as fire, flood, and internal dissension had all left their mark on the city, as predicted by the Buddha. Following the collapse of the Gupta Empire and continuous annexation by the Hunas, Patna experienced a period of uncertainty similar to the rest of India. The territory eventually came under the growing empire of Harshvardhana Samrat, who defeated the Hunsa and took control of the northwest region of India. However, during the 7th century CE, another Chinese pilgrim named Hiuen Tsang visited India and found Patliputra in ruins.

Medieval Period (13th Century to 17th Century)

In the 13th century, with the Turkish conquest of India and the establishment of the Delhi Sultanate, urbanization and cultural development began in Patna. The first Muslim invasion of Bihar occurred in the late 1190s under the rule of Bakhtiyar Khilji, which led to the expansion of Turkish rule in Bihar. From 1206 to 1526, Patna remained a secondary settlement that was subordinate to the town of Bihar. During the Mughal period, provincial administration reached its zenith. Patna re-emerged as a major centre of trade, but not as a capital city. One of its most remarkable periods was under the rule of Sher Shah Suri, who hailed from Sasaram and revived Patna in the mid-16th century. On his return from Bengal in 1541, Sher Shah arrived in Patna, and while standing on the bank of the river Ganga, he had a revelation that if a fort were built in that location, the water of the Ganges could not flow too far away from it, and Patna would become one of the great towns of the country. Sher Shah's words were put into action when he founded a fort in Patna, which enabled Patna to regain its identity as a hub of power and trade. However, the fort did not last, but the mosque built by him in 1545 survived, and it was built in Afghan architectural elegance with numerous tombs inside.

The earliest mosque in Patna dates back to 1489, built by one of the rulers of Bengal, Alauddin Hussani Shah. The locals call it Begu Hajjam's mosque in honour of a barber who repaired it in 1646. In 1574, the great Mughal emperor Akbar came to Patna to defeat Daud Khan, an Afghan chief. Akbar's secretary described Patna as a flourishing centre for paper, stone, and glass industries. He also mentioned the good quality of various strains of rice grown in Patna. In 1704, Patna was renamed Azimabad, after the grandson of Mughal emperor Aurangzeb, Azim, at the time when he was subedar of Patna (Boyk 2015). Other than the name, very little change

took place during that period. After the decline of the Mughal period, Patna was in the hands of the Nawabs of Bengal. At that time, the city was taken over by Jagirdars who claimed themselves as Nawabs. The Nawabs of Bengal imposed heavy taxes on people but allowed them to flourish commercially. During the 17th century, Patna became the hub of international trade. Much of the lost glory of Patna was revived during the medieval period, giving it a new identity as a medieval city in terms of function and structure under the Afghans and Mughals. The city almost emerged in the same area where it existed in ancient times.

British Period

Patna attracted the next generation of travellers, including Englishman Thomas Roe, who visited in the 17th century and spoke of the four rivers surrounding Patna, each of which served as a valuable waterway for trade. Ralph Fitch, a merchant, reached Patna in the 16th century via one of these riverine routes and observed a flourishing cotton and sugar trade, as well as the infamous opium business. Jean Baptiste Tavernier, a French traveller, visited in 1620 and described Patna as the largest town in Bengal and the most famous for trade, particularly for the exquisitely crafted coral and amber bracelets available in the city's market. By the 17th century, Patna had become a favourite port town for the Dutch, the British East India Company, and merchants from Central Asia, Armenia, and Portugal. In the 1620s, the British established a factory in Patna for the purpose of buying and storing cotton and silk, which soon became a bustling market for saltpetre (Hashmi, 2018). The French, Danes, Dutch, and Portuguese were all drawn to this attractive business, leading to the establishment of several European factories and godowns in Patna, which earned the reputation of being a lucrative location for merchants. In 1632, Peter Mundy declared Patna as the greatest mart in the eastern region. On October 6th, 1763, Nawab Mir Qasim was imprisoned and that led to killings of 45 members of the East India Company (Martin, 1838). Although they had been trading in Patna since 1620, when they established a factory for saltpetre, the British gained control of the city in 1765. After the Battle of Buxar, which took place 115 km west of Patna, the British East India Company was established in East India. Patna soon developed into a strategic centre for trade and regained its lost glory under British rule. Following the Delhi Darbar of 1911, the province of Awadh was divided, creating a separate province of Bihar, with Patna selected as its centre of power and capital city. No matter when, why, or for how long one visited, it was impossible to leave this city without a souvenir, be it a precious commodity from its market or an experience worth immortalizing in writing. After the partition of Bengal presidency

in 1912 (Ahmad, 1988), the city boundaries were extended westwards to include the administrative base and township of Bankipore, known as the New Capital Region. This era also saw the construction of two prominent landmarks, the Patna secretariate and the Patna High Court, designed by architect J.F. Munnings. Many buildings, reflecting either Indo-Saracenic influence or manifesting a Renaissance imprint, were completed by 1916-17. Pseudo-renaissance is expressed in the design of buildings like the General Post Office and the old secretariate. The British also built numerous educational institutions, including Patna College, Science College Patna, Bihar College of Engineering, and Prince Wales Medical College. Patna played a significant role in the Indian struggle for freedom, with notable contributions such as the Champaran Movement against Indigo plantation and the Quit India Movement of 1942.

Post-independence Period

Following India's independence, Patna's economic standing witnessed a sharp decline, particularly in the domain of trade and commerce. The region was predominantly ruled by Congress government from 1947 until the declaration of a state of emergency in 1975. The Bihar movement, led by students such as Jayaprakash Narayan, against the existing maladministration and corruption was initiated in 1974-75, and came to be known as the Sampoorna Kranti, or Total Revolution, and the JP movement. In the year 2000, Bihar faced a severe blow when Jharkhand, a state known for its abundant mineral deposits, was separated from Bihar. This led to a substantial loss in the revenue earned through mining and industrial activities. According to Bhattacharya (2000), while the state has been exploited and left destitute in the past, it could perhaps make up for the loss of mineral deposits by curbing the issue of rampant corruption within its governance structure. In effect, the Freight Equalisation Policy, which involved the transportation of mineral deposits to other states, has resulted in Bihar being underdeveloped. Despite a few challenges encountered during the post-independence, the economy of Patna remained relatively steady until the separation of Jharkhand from Bihar. The present scenario has led to an attempt at rejuvenation and the revitalisation of the region.

Growth

Throughout its history, Patna has experienced growth in various aspects despite its declining status. The earliest known map of the city dates back to 1776, a product of James Rennel for the British-controlled Bihar and Bengal province.

At the time, the city's settlement area was approximately 52 square kilometres. As of 1924, however, the administrative area had expanded by more than double, reaching a total of 142.46 square kilometres. Patna's population has grown more than tenfold since 1901. According to the Statistical Account of Bengal for Patna district in 1877, the city was situated between latitudes 24˚ 58' to 25˚ 42' north and longitudes 84˚ 44' to 86˚ 05' east. The district encompassed an area of 2101 square miles according to the Boundary Commission of 1875. The Census Report of 1872 indicated a population of 15,59,638 for the district (**Fig.** 2).

Spatial Growth

It is challenging task to track the absolute spatial growth of cities in developing nations due to a lack of adequate documentation. During the British period, Azimabad was the main town of Patna, as it was commonly called by the locals. The district of Patna was bounded by the Ganga river in the north, separating it from Tirhut and Saran; Shahabad district lay on the west, separated by the Son river; Monghyr (Munger) lay on the east, and Gaya lay on the south. The settlement and administrative area of Patna has been slowly but steadily expanding. According to toposheet data of Patna from 1924, the settlement covered an area of approximately 52 square kilometres. As per census records in 1961, the administrative area increased to 79.87 sq km (Table-1). The map of the province of Bihar and Bengal (**Fig.** 1) prepared by Major Rennel in 1776 indicates that Patna was an important riverine port city at that time (**Fig.** 3).

Due to this reason, the British colonizers gradually built their separate settlement to the west of the existing settlement. They strategically created military cantonment to protect their interests in trade and power. Britishers had always exploited the resources of Patna without considering the welfare of the city. Buchanan (1812), O'Malley (1907), and Forster (1924) had been critical of the city and its view from a distance was often termed as "mean," "disgusting," "disappointing," and other such derogatory terms. The series of maps for the years 1885, 1924, 1976, and 2009 show the spatial extent of Patna. The map of Patna from 1885 (**Fig.** 1) was prepared by Else Reclus and published in Nations and Nationalities of the World. Although Major Rennel's map does not align with the current system of latitudes and longitudes in modern map-making, it depicts the schematic settlements of Patna at that time. The native settlements mostly confined to the middle of eastern part of the city, between the southern bank of the Ganga in the north and the railway track in the south. Bankipur evolved as the settlement for Britishers, while Danapur cantonment can be seen in the north-western part of the city map.

He Survey of India has performed an outstanding task in mapping the Indian subcontinent's entire terrain in great detail since the British period. These topographical sheets have been invaluable for both military and civilian development purposes. In archives, three distinct toposheets of Patna have been discovered for the years 1924, 1976, and 2009. In 1924, the settlement area was primarily situated along the river Ganga (**Fig.** 2), and the railway line acted as an unofficial southern boundary of the city. Vegetation and water bodies were visibly present in the north-western and central regions, respectively. By 1976, the city had gradually expanded towards the south and south-west (**Fig.** 2), leading to the depletion of vegetation and water bodies during the mentioned period. The nalas of the central zone were severely impacted by the construction of government buildings in that area. The city rapidly expanded towards the west and north-west after 2001, as reflected in the settlement map of 2009 (**Fig.** 2). By this time, the spread of settlements had surpassed the official city limits, providing ample scope for urban sprawl.

Population Growth

Urban studies rely heavily on analysing population growth as a key determinant of the area's land use, infrastructure, and urban amenities. Patna has been a significant urban centre since the British era, as evident from **table-**1. In 1901, the population of the city was 1.8 lakh, which increased to over 2 million in the 2011 census and is expected to exceed 4 million by 2051. However, the rate of population growth has not been constant over time. The 1881 population enumeration recorded a population of 1,70,654, indicating a 7.4% increase of 1,58,900 in nine years. The increase was due to both natural growth and under-enumeration in 1872. In 1901, the population of Patna was 1,80,025. The city experienced stagnant or negative growth during 1911-1921 due to the Bengal famine. The census of 1911 was the last within the state of Bengal, while the 1921 census was the first as the capital city of Bihar and Odisha. Around 12.5 lakh people migrated from Bihar to Bengal in 1911, while around 1.65 lakh people immigrated (**Table-**1).

Post-1921, Patna's population growth fluctuated between 20-40%, indicating steady growth. However, it became a bumpy ride with rapid population growth from 1971-2001. **Table-**1 highlights that the Patna metropolitan city experienced tremendous growth rates in population during 1971-81 and 1991-2001 due to official expansion of the city boundary in adjoining areas. During 1971-81, the PRDA was formed, and three colonies were founded. The outgrowths and adjoining areas of Phulwarisharif, Digha-mainpura, and Danapur cantonment were included in this

agglomeration. During 1981-91, new colonies in Patna gradually expanded in open space within the city limits, which were included in previous official boundary expansion. Prior to the 2001 census, the city boundary was further extended. This time, the expansion was from Didarganj to Sherpur and Bailey road to Saguna more and Danapur junction. Apartment culture was on a boom during 1991-2001. Post-2001, the city boundary has remained unchanged, but the status of towns/outgrowths has been modified, and administrative units have been freshly demarcated during the census of 2011. The adoption of the concept of urban agglomeration dates back to the 1971 census, when it replaced the "town group" category. In the interest of developing plans and changing policies, the Government of Bihar has designated the Patna urban agglomeration as the Patna metropolitan city. Despite this, it was not until 1991, when the population exceeded 1.1 million, that Patna attained the status of a metropolitan area. In the 2001 census, Badalpura was identified as an outgrowth, while Patliputra housing colony and Saidpura were classified as census towns in the 2011 census. Previously, both of these towns had been considered as outgrowths. The expected population of Patna in 2051 is estimated to be around 4.3 million. However, due to its relative power status identity and strategic location,

the city may even exceed 5 million in the near future, largely due to the rapid influx of migrants. Survey results indicate that a significant number of Patna residents have migrated to the city over the past three decades.

Conclusion

The history and evolution of Patna, the capital of Bihar, is a captivating narrative that spans millennia, reflecting the city's deep-rooted cultural, historical, and geographical significance. Its origins are steeped in legend, with various names and tales that narrate its evolution from a small village named after the patli flower to the flourishing capital of the Mauryan Empire. This historical tapestry weaves folklore, divine intervention, and urban genesis into the fabric of Patna's identity. Megasthenes described the city as being located on the southern bank of the Ganges, at the confluence of the Son river which once joined the Ganges below present-day Patna. Memories of this junction still exist amongst the villagers to the southwest of Patna, where an old channel named the Mara Son flows. As time progressed, the city underwent significant changes, from the Mauryan period to the Shershah Suri era, ultimately becoming an essential strategic and trade centre for the British. The modern Patna has expanded exponentially since British times. Post-independence, the city faced economic challenges, and the separation of Jharkhand in 2000 led to a decline in revenue from mining and industrial activities. With the exponential growth in population and physical expansion of the city, the local administration is tasked with the challenge of providing basic urban amenities and maintaining the city's infrastructure. As the city continues to receive migrants from other areas, there is a shift in the land-use and land-cover patterns, resulting in urban sprawl beyond the city limits.

Between 1924 and 2022, the Patna metropolis has undergone a nearly threefold expansion, specifically from 51.46 to 142 square kilometres. Correspondingly, the demographic landscape has witnessed significant growth, with the city's population escalating substantially from 1.8 lakh in 1901 to 20.5 lakh in 2011. However, notwithstanding these pronounced spatial and demographic advancements, the city exhibits a deficiency in terms of fundamental industrialization. As Patna looks towards the future, it is poised for further growth and development, with its strategic location and historical significance continuing to shape its trajectory. The city's journey from ancient legends to a modern metropolis underscores its resilience, adaptability, and enduring importance in the cultural and historical landscape of India.

BIOLOGIC EFFECTS OF INGESTION OF NITRATE IN DRINKING WATER AN OVERVIEW OF INDIA

Narender Singh, Dr. Ranjeet Kumar and Prof. Tribhuvan Prasad

Abstract

Nitrate pollution in surface or subterranean water is a pervasive global issue, particularly prevalent in agrarian nations. Undoubtedly, regions most susceptible to climatic shifts face heightened vulnerability owing to their geographical disposition. Unfavorable topographic features and uncertainties in hydro-meteorological conditions amplify the extent of contamination. Given that nitrate pollution in our potable water sources is pandemic and the costs linked to purifying these water sources are exorbitant, exposure to elevated nitrate levels significantly contributes to deleterious health consequences that necessitate attention. This manuscript delves into the biological ramifications of surplus nitrate in our drinking water and the diverse array of human health concerns in India and various pivotal parts of the globe. In a bid to forestall methemoglobinemia, an acute toxic response to nitrite exposure impeding oxygen transport via the bloodstream, the US EPA (Environmental Protection Agency) has designated the maximum admissible nitrate level in drinking water at 10 mg nitrate-N/L. However, it's a common occurrence for surface and subterranean water in agricultural regions to surpass this standard periodically and/or over extended durations. While a definitive correlation between nitrate consumption and cancer remains elusive, some indications suggest a potential linkage. The magnitude of health risks posed by nitrate contamination in drinking water remains a subject of debate. Groundwater stands as a vital water source for both domestic and agricultural usage on a global scale. It serves as the primary domestic water source for 50% of the world's populace and nearly 90% of rural inhabitants. A substantial 75-80% of water used for agricultural irrigation originates from groundwater. Safeguarding groundwater against nitrate pollution presents a multifaceted managerial challenge necessitating effective policy alignment at federal, state, and local echelons, particularly due to the inherent complexity of groundwater purification. Moreover, these challenges are compounded by varying levels of awareness, socio-economic development, low literacy rates, high poverty, and the inclusion of cultural practices and rituals, all of which exacerbate the intricacies of the endeavor.

Introduction

Ensuring safe drinking water remains crucial for public health, a fundamental human entitlement. Regrettably, this right falls short of people's expectations. Water, an essential element, faces an impending challenge as research indicates an upward trajectory in nitrate levels. This concern extends beyond rural communities, impacting major urban centers reliant on bore water. The solubility and biodegradability of nitrates contribute significantly to their increased presence in water bodies. The consequential decline in both quality and quantity of water bodies persists due to the heavy reliance on synthetic fertilizers, sewage, industrial waste, and livestock manure. Guidelines from the US EPA's nutrient data policy reveal the distinct markers of nitrate presence. While nitrates occur naturally at very low levels (<1mg/L NO3-N), levels exceeding 1mg/L NO3-N are indicative of human activities. Concentrations surpassing 3mg/L NO3-N generally signal groundwater contamination. In India, the Bureau of Indian Standard (BIS) stipulates the Maximum Contaminant Level (MCL) for nitrate in public drinking water supplies at 45 mg/L as nitrate (NO3-), nearly akin to the WHO guideline of 50 mg/L as NO3- or 11.3 mg/L NO3-N (derived by multiplying NO3 mg/L by 0.2258).

Interestingly, this MCL, initially set in 1962 by the US EPA to prevent infant Methemoglobinemia, lacks considerations for other potential health impacts. A crucial issue with the current MCL for nitrate in drinking water is its obsolescence, particularly its lack of association with colorectal cancer, thyroid ailments, or neural tube defects. Consequently, a more lenient limit of less than 10mg/L NO3-N was established as a generalized threshold for nitrate contamination, offering a lax aspiration level within this range. This distinction between actual safety and mere cleanliness holds immense significance. It delineates a fine line between life and death, between improved health and the burden of costly medical bills for young families, and between mere survival and flourishing for entire communities. Nitrate, prevalent in various foods, peaks in green leafy vegetables like spinach and celery, as well as root vegetables such as beetroot. Daily intakes from food range from 30-130 mg/day as NO3- (7–29 mg/day NO3-N) (ICAR, 2020). Once consumed, most of the ingested nitrate travels through the body and is absorbed into the bloodstream via the small intestine. Approximately 25% of the nitrate in the blood is transformed into nitrite through a reduction process in saliva. While most nitrite is absorbed into the blood and converted into beneficial compounds, a fraction may form potentially harmful N-nitroso compounds.

Study Region

Indeed, nitrate pollution stands as one of the oldest and most financially burden some environmental issues, both regionally (India) and globally. Several contributing factors underline this reality: A notable surge in population, from 5.3 billion to 7.7 billion between 1990 and 2020, with projections foreseeing a rise to 9.7 billion by 2050 (UN, 2020). The onset of increased industrial activities since the mid-19th century has significantly amplified pollution and deterioration of water resources (Bond et al., 2018). Climate change exacerbates water stress globally, particularly in arid regions, through diminished rainfall, leading to severe droughts and erratic rainfall patterns during the rainy seasons (Lorite et al., 2018; WHO, 2012). In recent years, ensuring access to clean drinking water for communities has become increasingly challenging due to the emergence of new water quality issues. Groundwater sources, vital for global agri-businesses, industries, and drinking water needs, face mounting pressure amid growing scarcity concerns and fears of microbial contamination. Nitrate contamination, prevalent in agricultural and densely populated regions, notably affects the Indo-Gangetic Plain (IGP), recognized as one of the world's largest alluvial aquifer systems (MacDonald et al., 2016). Spanning approximately 52 million hectares, it supports a population of 500 million across Delhi, Haryana, Punjab, Bihar, Uttar Pradesh, and West Bengal according to the 2011 Census.

The northwestern segment, marked by intensive agricultural practices and widespread nitrogen-based fertilizer use, exhibits significant groundwater contamination hotspots. India grapples with 20 identified nitrate hotspot areas, each displaying varying average nitrate levels. Some regions indicate averages below 50 ppm, while others range between 59 and 215 mg/L, showcasing considerable data variability (Devaraj et al., 2020; Pant et al., 2020). Notably, values surpassing four times the WHO-recommended standard are reported in certain areas, such as Birbum in West Bengal (44 & 45), Solapur in Maharashtra (66 & 71), and Bareilly in Uttar Pradesh (31 & 51), with reported average values spanning from 7 to 47 mg/L. Even within these regions, over a quarter of samples exhibit nitrate concentrations exceeding 50 mg/L (Hossain & Patra, 2020; Mazhar & Ahmad, 2020; Mukate et al., 2019). The causes of pollution in the country are attributed to various factors, including inadequate maintenance of septic tanks, boreholes, sanitation, and fertilizer use, as highlighted by several authors (Barbieri et al., 2019; Devaraj et al., 2020; Roy et al., 2020).

Objectives

(1) This study aims to conduct a health risk assessment of nitrate in distributed drinking water in India and across significant global regions.

(2) Assessing what needs to be done to ensure an adequate drinking water supply throughout the country & what can be done in managing land & water to limit nitrate pollution.

Database and Methodology

The interest in studying groundwater health, particularly concerning nitrates, has seen a significant surge since the early 1980s. From an average of 100 articles per year globally in the 1970s and 1980s, the scientific community published 2742 articles in 2020 on this subject. In India, the Integrated Management Information System (IMIS) was established in 2009 alongside the National Rural Drinking Water Programme (NRDWP), creating a web-based platform for annual online monitoring of water supply projects and rural coverage. Sarkar et al. (2021) investigated the spatial variation of nitrate content in Indian groundwater using data from the NRDWP database. Various studies nationwide have sampled groundwater from wells, boreholes, and springs primarily used for irrigation or domestic purposes (Devaraj et al., 2020; Hossain and Patra, 2020; Mazhar and Ahmad, 2020; Mukate et al., 2019). However, several nitrate-contaminated areas, particularly within the Indo-Gangetic Plain, were not adequately covered in individual studies, posing a significant limitation. Larger-scale or national studies are necessary to comprehend the extent, spatial distribution, sources, and health impacts of groundwater nitrate contamination, mandating efficient local governance and management. Yet, a comprehensive detailed interpretation required for this remains lacking. Despite numerous articles published until December 2021 detailing groundwater quality parameters, a comprehensive understanding of nitrate pollution and its health impacts at the local level remains elusive. Conducting a comprehensive research and assessment of the health effects of groundwater nitrate contamination at the local level is a novel undertaking. This review delves into nitrate sources in groundwater, its health implications, and focuses on human health risk assessment. Such a study is pivotal in understanding the challenges India faces in achieving Sustainable Development Goals (SDGs) 6.3 outlined by the United Nations in 2015.

Result and Discussion

Methemoglobinemia

Methemoglobinemia, linked to elevated nitrate levels in drinking water used for infant formula preparation, was initially documented in 1945 (Comly H.H. et al., 1945). When ingested, bacteria in the mouth and the less acidic infant stomach convert nitrate to nitrite. Nitrite, in turn, binds with hemoglobin, forming methemoglobin, which disrupts the blood's capacity to carry oxygen. Methemoglobinemia is a severe condition, posing a life-threatening risk when methemoglobin levels exceed approximately >10 mg/L NO3-N. Risk factors for infant methemoglobinemia encompass formula prepared with water containing high nitrate levels, along with foods, medications, and enteric infections that exhibit high nitrate levels. non-existent in these areas.

Adverse reproductive outcomes: (spontaneous abortions)

There have been several studies examining spontaneous abortions, linking high maternal methemoglobin levels caused by elevated nitrate ingestion to miscarriages in laboratory animals and livestock. An intriguing 1996 Center for Disease Control (CDC) of Morbidity and Mortality Weekly Report (MMWR) report documented a cluster of spontaneous abortions among women using private wells in rural Indiana, where nitrate levels exceeded twice the Maximum Contaminant Level (MCL) of 20 mg/L NO3-N. When these women switched to low-nitrate water sources, they experienced healthy live births. While this wasn't a formal study, the evidence was compelling, suggesting the involvement of high-nitrate water in the miscarriages. Interestingly, a separate study in Massachusetts found no association between spontaneous abortion and lower nitrate levels below 5.5 mg/L NO3-N, indicating divergent findings in different settings Indeed, there's been documentation of a heightened incidence of infant methemoglobinemia in Eastern Europe, as noted previously (Ayebo A. et al., 1997). A 2002 WHO report on water and health highlighted significant cases in the region: 41 cases annually in Hungary, 2913 cases in Romania spanning 1985–1996, and 46 cases in Albania in 1996. Generally, nitrate levels surpassing >10 mg/L NO3-N were often linked to increased methemoglobin levels, though clinical methemoglobinemia wasn't consistently present (Fig-1). In India, methemoglobinemia is relatively uncommon, possibly owing to limited awareness or a scarcity of epidemiological studies on the disease. It's intriguing that in a country where agriculture is a predominant livelihood and where sanitation remains inadequate in numerous regions, reported instances of methemoglobinemia are rare (**Fig.** 1).

Birth Defects and Cancers

According to a 1995 IARC report, over 300 nitroso compounds were tested in animals, with about 90% found to be carcinogenic. These compounds showed carcinogenicity across various animal species, including non-human primates, suggesting a likelihood of impact on humans. These nitroso compounds have the potential to induce tumors in multiple organs such as the lungs, digestive tract, urinary tract, and some reproductive organs. Exposure during pregnancy can lead to congenital malformations, particularly affecting the Central Nervous System, especially during the critical phase of organ development in the first trimester. Shifting focus to cancer, in 2006, an IARC working group assessed the evidence for the carcinogenicity of ingested nitrate and nitrite. Their conclusion stated that under conditions conducive to the formation of N-nitroso compounds or endogenous nitrosation, nitrate and nitrite were deemed probably carcinogenic to humans. The evaluation drew from compelling evidence obtained through animal studies, where carcinogenicity was consistently observed across all species tested in laboratory settings. Additionally, human mechanistic studies provided further support. These studies indicated that exposure to nitrosamine compounds increased with nitrate ingestion, either through drinking water or controlled intake experiments. It was demonstrated that nitrate ingestion led to heightened exposure to nitroso compounds, measured by their excretion in urine. This correlation between nitrate intake and increased presence of these compounds provided robust evidence supporting the evaluation's conclusions.

Case-control or Cohort Studies of Drinking Water Nitrate and Cancer Studies

(1) Colorectal:5 studies (4 Positives)
(2) Brain(Children/young adults):3 studies (3 Positives)
(3) Bladder:4 studies (2 Positives)
(4) Kidney: 2 studies (2 Positives)
(5) Non–Hodgkinlymphoma:3 studies (1 Positives)
(6) Pancreas: 2 studies (0 Positives)
(7) Brain (adults): 2 studies (0 Positives)

In terms of epidemiological studies, investigations into dietary nitrate consumption didn't yield any association with an increased risk of cancer. However, when it comes to drinking water, the evidence was deemed inadequate due to the limited number of studies available.

Presently, the strongest evidence from epidemiological research suggests a positive association between nitrate exposure and colorectal cancer, with four out of five studies demonstrating such a link. Similarly, concerning childhood brain tumors (including young adults in one study), all three available studies indicate a positive association, with two of these studies conducted or published within the past year. However, for other cancer sites, there's notably less evidence available.

Nitrate in Drinking Water and Hypothyroidism:

In terms of biological plausibility, the concern doesn't solely revolve around nitroso compounds, but also involves nitrate's potential to impede iodine uptake by the thyroid. Three studies showed positive associations between higher water nitrate ingestion and related health issues: A study conducted on school-age children in Slovakia revealed an increased prevalence of subclinical hypothyroidism in areas with high water nitrate levels (ranging from 51 to 274 mg/L NO3-) compared to areas with nitrate levels at or below 50 mg/L (11 mg/L NO3-N) in water supplies (Tajtakova M. et al., 2006). A cohort study of post-menopausal women in Iowa found that higher nitrate intake, both through diet and drinking water from Public Water Supplies, was linked to an increased prevalence of hypothyroidism (Ward M.H. et al., 2010). An Amish cohort study in Pennsylvania discovered that among women, but not men, higher water nitrate levels (>6 mg/L NO3-N) were associated with elevated thyroid stimulating hormone (TSH) levels and a greater prevalence of subclinical hypothyroidism (Aschebrook-Kilfoy B. et al., 2012).

The primary human-caused sources of nitrate contamination fall into five categories: septic tanks, sewage, agriculture, landfills, and industrial activities. Often, nitrate pollution occurs alongside contamination by fluorine, sulphates, potash, phosphates, and heavy metals like zinc, cadmium, or arsenic. This pollution is frequently concentrated in areas reliant on agriculture for income or where sanitation infrastructure is lacking. Beyond these sources, various catastrophic events in recent decades have altered nitrate levels in groundwater in affected regions. For instance: The groundwater near the Union Carbide factory in Bhopal has faced excessive nitrate, chloride, and heavy metal contamination. ("Water Contamination Crisis - Bhopal's Second Disaster - The Bhopal medical appeal", 2021) The Beirut explosion in 2020, caused by inadequate storage of 2750 tons of ammonium nitrate, released a substantial amount of pollutants into the environment. Following the Chernobyl accident, two regions in Belarus reported similar radiation levels, yet the incidence of pediatric thyroid cancer differed significantly due to variations in nitrate contamination in drinking water, measuring 40 vs. 185 ppm (Drozd et al., 2018).

This escalating pollution trend requires immediate and drastic solutions to prevent further degradation of natural water bodies, particularly in developing countries like India, where water shortages exacerbate the issue. Urgent actions are essential to avert the complete deterioration of these vital water resources.

Conclusion

This review examines the water quality of various groundwater bodies throughout the country in terms of nitrate concentrations, discusses various health issues for both this compound and other important pollutants. On the basis of which some general conclusions can be drawn.(1) The occurrence of nitrates in groundwater continues to increase and urgent measures are therefore required to prevent nitrates from breaking down into water particles. (2) Levels exceeding the WHO standard (50 ppm) exist in various parts throughout the country. (3) Nitrate pollution from agriculture, especially the use of fertilizers and pesticides, is common across the nation. (4) In India, large fluctuations in NO3- concentration are observed due to the strong influence of the rainy season and insufficient treatment of septic tanks. (5) In addition to pollution from fertilizers, wastewater discharged without proper treatment & industrial activities contribute significantly to the occurrence of nitrates in groundwater. (6) Apart from the various reasons summarized above, environmental pollution is mainly due to poor health conditions in many parts of India (e.g. the presence of untreated septic tanks). Currently, there are many surface water treatment facilities, but the number of groundwater treatment facilities is still very limited and further research is needed into different treatments for nitrate removal. Recent studies on cancer and birth defects have started identifying population subsets prone to internal nitrosation, but direct methods for identifying these individuals are necessary. New approaches in epidemiological research, such as detecting nitrate-reducing bacteria in the oral micro biome and studying genetic variations in nitroso compound metabolism, hold promise in identifying high-risk individuals. However, a lack of comprehensive studies on individual health impacts hampers definitive conclusions about the risks of consuming nitrates through drinking water. Further investigation is crucial, especially in refining exposure assessment for users of public water systems, understanding exposure levels among those using private wells, quantifying nitrate-reducing bacteria, and assessing various factors influencing nitrosation. Focusing on conditions like colorectal cancer, thyroid disease, and central nervous system birth disorders, consistently associated with nitrate ingestion from water, will significantly contribute to clarifying these concerns.

A GEOGRAPHICAL ANALYSIS OF CROP CONCENTRATION IN PRAYAGRAJ DISTRICT

Neha Yadav and Dr. Sangeeta Chauhan

Abstract

This study focuses on analyzing crop concentration in Prayagraj District, encompassing all 20 blocks. Secondary data from the year 2020-21 was utilized for this research. Crop concentration is crucial in understanding the suitability of specific areas for particular crops, particularly considering changes in agricultural land use and shifts in crop proportions. Crop concentration has been determined using the Bhatia's location quotient technique. This technique identifies changes in agricultural land use by examining shifts in the proportion of land allocated to various crops. The study calculated the amount of area involved in these changes, highlighting the crops with the most significant increases and decreases. The data obtained is used to create thematic maps, providing a spatial representation of crop concentration in the district. Crop concentration is categorized into four sections: High, Medium High, Medium and low. These categories help depict the intensity of land utilization and identify areas suitable for specific crops. One significant determinant of cropping patterns is irrigation, which generally has a positive influence on the intensity of cropping. The study observed substantial variations in land use and cropping patterns across the study area. Wheat and Rice emerged as the dominant crop throughout the district, in terms of total agricultural production. This research sheds light on the changing cropping patterns and land utilization in Prayagraj District, providing valuable insights into the suitability of different areas for various crops. The findings can inform agricultural planning and land-use policies in the region, helping optimize crop production and land utilization.

Introduction

Crop concentration, as defined by TS Chauhan in 1987, pertains to the spatial distribution of individual crops within a specific area. It serves as an indicator, revealing the variability in crop density within a given region at a particular moment in time.

The delineation of crop concentration assumes paramount importance in the realm of agricultural planning and development. The cropping pattern observed in any region is intricately woven with a tapestry of influences, including geo-climatic, socio-economic, historical, and political factors, as noted by M. Hussain in 1996. Moreover, technological factors have emerged as influential forces shaping these patterns. Terrain, topography, slope, soil composition, and the presence of irrigation facilities all contribute to the diversity of cropping patterns. The use of pesticides, fertilizers, and mechanization further compounds these complexities. Understanding the myriad factors that influence cropping patterns, from natural elements to human interventions, is fundamental for effective agricultural planning and development. The various geographers applied location quotient methods to work out the degree of Crop Concentration in a specific region. The geographers pioneer work of Chisholm (1962), Bhatia (1965), Jasbir Singh (1976) are the contributors to make the agricultural region with the help of quotient method. In this research work, Bhatia's method has been adopted to measure the index of Crop Concentration in Prayagraj District.

Study Region

Latitudinal and longitudinal extent of Prayagraj District is 24°47' N to 25°45'N and 81°31'E to 82°21'E in the south of Uttar Pradesh State at an elevation of 98 meter (322 Ft) and is situated at the confluence of Ganga and Yamuna. To its south and southeast is the Baghelkhand region, to its east is middle Ganges valley of North India, to its southwest is the Bundelkhand region, to its north and northeast is the Awadh region and to its west along with Kaushambi it forms the part of doab i.e. the lower doab region. Prayagraj has a humid subtropical climate. It experiences three seasons in a year. The summer lasts from April to June, monsoon begins in in early July and lasts till September, and the winter season lasts from December to February. The Ganga and Yamuna are the main rivers of the district. The plain area of the district is situated in between Ganga and Yamuna so these rivers play a very pivotal role in the agriculture of the district. The main staple crop of Prayagraj is wheat and rice. According to 2011 census, population of the study area is 5,954,391 of which male and female were 3,13,807 and 2,822,584 respectively. Population growth rate was 20.63% compared to 2001 census. The headquarter of the district is Allahabad City. The district is divided into blocks and tehsils. As of 2011 census there are 20 blocks in 8 tehsils. The total area of the district is 5,482 sq. km. The number of villages is 3003 according to Prayagraj statistical bulletin.

Objectives

(1) To analyze the crop concentration and its variation in Prayagraj District.

(2) To identify the areas of crop concentration in the basis of Bhatia's method.

Database and Methodology

The research work is based on the secondary data obtained from UP statistical Bulletin, Prayagraj (2020-21). Various thematic maps related to cropping patterns are prepared with the help of GIS. In order to determine block wise crop concentration Bhatia's method has been used.

Crop Concentration Index: = (a/b)/(A/B)

Whereas:

a= area of crop 'a' in the component areal unit

b= area of all the crops in the component areal unit

A= area of crop 'a' in the entire region

B= area of all crops in the entire region

Here, the higher index values represent a high level of crop concentration and low values show the low concentration of crop

Crop Concentration Pattern

Rice: It is a staple crop that serves as a primary food source for more than half of the world's population. Paddy is the second most important food grain in Prayagraj district it is cultivated in the kharif season. Moderate temperature and high rainfall is required for its cultivation. Rice cultivation supports the livelihoods of millions of farmers worldwide, it is a source of income and employment for rural communities. Rice is a major agricultural commodity in international trade, contributing significantly to the economies of exporting countries. In 2020- 21, total area under paddy cultivation was 155655 hectares. Paddy is cultivated in all the blocks of Prayagraj district. The blocks having medium high concentration of paddy are Jasra, Shankargarh, Meja, Manda, Holagarh, Mauaima, Soraon, Phulpur Pratappur and Dhanupur. Rest of the blocks have medium concentration of rice. Medium high concentration is in the northern and southern regions of the study area except Koraon and medium concentration is in the centre of the district.

Wheat: Wheat is the most important crop in Prayagraj. It is a Rabi crop it requires cool temperature and moderate rainfall, wheat is harvested in the summer

Table-1: Crop Concentration Index of Rabi Crops in Prayagraj District

Source: Calculated and compiled by Authors.

when the grains have fully developed and turned golden brown, modern machinery such as combine harvesters is used for efficient harvesting. Wheat is a primary source of carbohydrates for a significant portion of the world's population. It is a staple food in many countries and is used to make a wide variety of products, including bread, pasta etc (**Table-**1). Wheat is a fundamental component of the world's food

supply. Reliable wheat harvests help stabilize food prices and ensure a consistent food supply enhancing global food security, therefore good concentration of wheat is very crucial for famer and other people. The total area under wheat cultivation in 2020-21 was 249902 hectares. Blocks having medium high concentration are Phulpur, Pratappur, Handia, Jasra, kaundhiyara, Meja and rest of the blocks have medium concentration. Medium high concentration is in the south and north east in Prayagraj District and medium concentration is in the northwest of the study area (Fig-1).

Barley: Barley holds significant importance due to its various uses and nutritional benefits, it is rich in dietary fiber, vitamins and minerals and has low glycemic index. Farmers often cultivate barley for both human consumption and livestock feed, enhancing agricultural productivity. In Prayagraj barley is grown in winter season. In Prayagraj total area under Barley is 2062 hectares (2020-21). In the district blocks having high concentration are Bahadurpur, Chaka Karchhana, Uruwa and Manda the block having medium high concentration are Kaudihar, Saidabad, Handia and blocks having medium concentration are Soraon, Pratappur, Dhanupur, Shankargarh, Meja and Koraon. Rest of the blocks have low concentration.

Vegetables: The vegetables grown in Rabi season are tomato, potato, onion, cauliflower spinach, radish green peas etc. The blocks having high concentration of these vegetables are Holagarh, Mauaima, Kaudihar, Baharia, Soraon, Pratappur, Saidabad, Dhanupur, Handia, Chaka and the block having medium high concentration of Rabi vegetables is Bahadurpur. Rest of the blocks have low concentration. The vegetables grown in Kharif season are bitter gourd, bottle gourd, brinjal, green beans, sponge gourd etc. Blocks having high concentration are Kandahar, Holograph, Bahrain, Manama, and Soprano. The blocks having Medium High concentration are Philpot, Pratappur, Bahadurpur, and Handia. Blocks having medium concentration are Dhanupur, Chaka. Rest of the blocks have low concentration.

Sorghum: Sorghum, also known as jowar in India, is a versatile cereal crop that holds significant importance in the country. Sorghum is drought- resistant, making it crucial crop in regions prone to water scarcity. It can withstand harsh weather conditions, ensuring food security in arid and semi-arid regions. This is a kharif crop, the blocks having high concentration are Shankargarh, Meja, Uruwa, Chaka, Karaon and Meja, the block having medium high concentration is Handia. Mauaima and soraon have zero concentration of Sorghum. Bahadurpur, Pratappur, Saidabad, Dhanupur, Jasra, Kaundhiyara and Manda have medium concentration, rest of the blocks of low concentration (**Table-**2).

Table-2: Crop Concentration Index of Kharif Crops in Prayagraj District

Pearl Millet: Pearl millet is known as Bajra in India. Bajra is rich in protein, fiber, vitamins, and minerals, making it a valuable dietary staple, especially in regions with poor soil quality and limited access to other nutritious food. This is also a drought resistant crop, many small scale farmers rely on bajra cultivation for their subsistence, providing a source of income and sustenance for their families. This is grown in kharif season the blocks having high concentration are Soraon,

Bahadurpur, Karchhana, Saidabad, Kaudihar, Baharia and Uruwa. The blocks having medium high concentration are Handia and Chaka. Meja has medium concentration of Pearl millet, rest of the blocks have low concentration.

Maize: Maize is a staple food for millions of people in India. It is consumed in various forms, such as corn on the cob, popcorn, and makki di roti. This is a droght resistant crop making it suitable for cultivation in regions with irregular rainfall patterns. Maize crop yields a high quantity of grains per hectare, contributing to agricultural productivity. It is grown by both small scale farmers and commercial agricultural enterprises. In Prayagraj, Maize is grown in kharif season, this is rainfed crop, Pratappur, Saidabad, Dhanupur, Handia and Koraon have high concentration of maize. Holagarh has medium high concentration. Baharia, Phoolpur and Manda have medium concentration.

Pulses: Pulses are a primary source of protein for millions of vegetarians in India. They are essential for fulfilling the protein requirements of a predominantly vegetarian population. The pulse industry creates employment opportunities in rural areas, including processing, trading, and transportation, contributing to the rural economy. Pulses cultivated in Prayagraj are Urad, Arhar, Masoor and Chana, the most important among them is Arhar or Pigeon Pea. Arhar dal requires a warm and tropical climate, moderate and well distributed rainfall, well-drained soil, abundant sunlight, and careful management of pests and diseases. The total area under arhar is 14639 hectares (2020-21). Chaka, Karchana and Koraon have high concentration. The blocks Jasra and Uruwa have medium high concentration. Kaudihar, Handia, Saidabad Shankargarh, Kaundhiyara, Meja and Manda have medium concentration. Rest of the blocks have low concentration. Out of 20, 7 blocks have medium concentration of Arhar in Prayagraj District.

Sugarcane: Sugarcane is the primary source of sugar production in India. Sugarcane cultivation and the sugar industry contribute significantly to the Indian economy. India is one of the largest producers of sugarcane and sugar in the world. Sugarcane farming provides employment to millions of farmers and labourers, especially in rural areas. Sugarcane is a long duration crop and requires 10 to 14 months to mature depending upon the geo- climatic conditions, it require 75 to 150 cm rainfall and in average 21 degree to 27° C temperature for better growth in 2020-21 total area under sugarcane cultivation was 666 hectares, the blocks Karchhana, Dhanupur, Pratappur and Mauaima have high concentration. Soraon, Phulpur, Handia have medium high concentration. There is no cultivation of sugarcane in Shankargarh, Chaka and Jasra. Baharia, Kaundhiyara and

Manda have medium concentration. Rest of the blocks have low concentration index of sugarcane in Prayagraj District.

Oilseeds: The most important oil seed in Prayagraj district is mustard. This is usually sown in the winter season from October to December, mustard prefers cool and dry weather during its growth period. Moderately drought resistant but requires adequate moisture during its early stages. The blocks having high crop concentration are Karchhana, Chaka and Koraon. The block having medium high concentration are Bahadurpur, Jasra and Meja. Rest of the blocks have low concentration of mustard crop. Other oilseeds grown in the district are Sesame and Flaxseeds. Sesame is cultivated in all the blocks of the district while flaxseed is cultivated only in 8 blocks of the district.

Fodder: The choice of fodder crop depends upon climate soil type and livestock requirements. For any region fodder plays a crucial role in supporting the livestock population. Fodder is crucial for dairy farming. Well-nourished dairy animals produce higher quantities of milk, supporting the dairy industry and ensuring a regular supply of milk and dairy products for consumers. In the district most of the fodder is grown in kharif season covering 2753 hectares (2020-21) of the total crop area. Two blocks have high concentration, they are Bahadurpur and Handia. The blocks having medium high concentration are Kaudihar, Soraon, Phulpur, Pratappur, Saidabad, Dhanupur, Shankargarh and Manda. The blocks Holagarh, Baharia, Karchhana, Uruwa and Koraon have medium concentration, rest of the blocks have low concentration. Crop concentration index of fodder in the blocks are mostly in medium high and medium range.

Conclusion

The variations in the concentration of Crop cultivation across the study region can be attributed to a complex interplay of factors, including geographical features, climate, water resources, socio-economic conditions and technological influences. These factors collectively contribute to the special distribution pattern of crops in the area. According to research analysis there is not much difference in crop concentration pattern of rice and wheat in the blocks of Prayagraj, this can be attributed to almost similar physical features across the district. High concentration of Barley can be seen in the centre of Prayagraj, only the 25% of the total production of Barley is irrigated. High and medium high concentration of vegetation of both Rabi season and Kharif season is in the Northern portion of the district. Medium high concentration of Sorghum is in the southern portion of the district,

it is a completely rainfed crop. High concentration of sugarcane is observed in east of the district and in Mauaima block which is in northern region of Prayagraj. High concentration of mustard is observed in the centre of the district in northwest and in southern block (Koraon). We can observe that crops like wheat and rice have almost even concentration and the other crops like barley, sorghum, pearl millet, maize, pulses, sugarcane and oilseeds have uneven distribution. This is because wheat and rice is the staple crop of Prayagraj which supports them financially and provides sustenance and other crops are cultivated by the choice of farmers where they have favorable conditions.

SOCIO-ECONOMIC STATUS OF THE VANTANGIYA COMMUNITY: A CASE STUDY OF VANTANGIYA VILLAGES IN MITHAURA BLOCK OF MAHARAJGANJ DISTRICT

Ruchika Singh and Vaibhav Tripathi

Abstract

The Vantangiya community is a community based on economic activities, which the Britishers settled between the 1920s and 1930s to plant and protect Sal and Teak trees in the Terai areas of the states of Uttar Pradesh and Uttarakhand to meet their economic and infrastructural needs. Since the beginning, the people of this community have been living a displaced life; they were displaced from one place to another in an interval of about five years to plant and protect trees like bonded labours. More or less, this situation remained the same even after the country got independence. The Vantangiya community has been a victim of socio-economic deprivation for many years, and they have struggled a lot to get their rights. The current study examines the socio-economic status of the Vantangiya community in the Mithaura block of Maharajganj district. Socio-economic status of the different villages of the Vantangiya community was identified using the Socio-Economic Index which was constructed by the composition of various socio-economic factors like health, demographic characteristics, education, income-expenditure ratio, land ownership, etc. Variables of all these socio-economic factors and their values are pre-assumed and the value of Standard Socio-Economic Index (SEI) has been calculated on the basis of standard values of all these variables. Based on the value of the Standard Socio-Economic Index, a comparative analysis of the socio-economic status of the five villages of the Vantangiya community is analysed in this study.

Introduction

"Socio-economic development is a process of quantitative, qualitative and structural changes that are a result of actions of subjects taken within social(economic) practice. These changes influence life conditions in the following fields: material conditions (possibility to satisfy needs associated with consumption

of goods and services; it is related with the phenomena of economic growth), economic structure and entrepreneurship, access to public goods and services (that results in changes of education level, a way of taking care of someone's health etc.), relation within social system (integration between individuals, trust, security, social conflicts), environment condition and life satisfaction." Its goal is to maintain the region and its people's social and material well-being in order to achieve the optimal level of human development. Development, in the socio-economic context, refers to the improvement of people's standard of living through better employment, income, skills, and development opportunities. Thus, socio-economic development is the process by which a society develops both socially and economically. Health care facilities, sanitization, the availability of clean water, literacy, the income-to-expenditure ratio, and land ownership are some indicators used to measure it. A person's or group's socio-economic status is a combined economic and social measure of their position about others based on their health, education, and occupation. Socio-Economic status consistently and accurately predicts a wide range of outcomes throughout a person's life. A community is a social group that shares common things like area, traditions, beliefs, values, and identity. Communities may share a sense of place in a specific geographic area (like a country, hamlet, town, or neighbourhood) or virtual space through many communication platforms. According to the given definition of community, a community developed based on economic activities in the state of Uttar Pradesh and Uttarakhand of India in the first half of the 20th century is called the Vantangiya Community. Natural forests were extensively cleared for railway tracks some 100 years ago in this region when India was ruled by the British. Based on the Tangiya technique, a farming strategy used in the mountains of Myanmar, the British chose to create a forested area in its place. Many labourers were brought to the forest for this purpose from the villages of the Gorakhpur division. As a result, they were given the name "Vantangiyas"; "Van" signifies forest, and "Tangiya" comes from the words "tongya" where "tong" means mountain and "ya" belongs to the agricultural area. In Uttar Pradesh and Uttarakhand, the Tangiya system was implemented between 1920 and 1923. More than 5,000 Vantangiya families live in 23 forest villages in Gorakhpur and Maharajganj districts. Since the beginning, the people of this community have been living a displaced life; they were displaced from one place to another in an interval of about five years to plant and protect trees like bonded laborers. More or less, this situation remained the same even after the country got independence. The Vantangiya community has been a victim

of socio-economic deprivation for many years, and they have struggled a lot to get their rights. Due to the prohibition on their primary economic activities for the past several decades, they were forced to lead a displaced life, but for some years, through governmental and non-governmental efforts.

Study Region

Maharajganj district is situated north-eastern Tarai part of Uttar Pradesh in India. Its boundaries touch Nepal Estate in the north, Gorakhpur district in the south, Kushinagar district in the east, and Siddharth Nagar and Sant Kabir Nagar districts in the west. The total area of this district is 2952 square kilometers. Based on the census of 2011, the total population of this district is 26,85,292. Maharajganj was a tahsil of Gorakhpur and became a district on 2 October 1989. Maharajganj district consists of 12 Vikas khand blocks- Partawal, Paniwara, Pharenda, Dhani, Brijmanganj, Nautanwa, Lakshmipur, Mithaura, Nichlaul, Siswa Bazar, Ghughuli & Maharajganj Sadar. Vantangiya community lives in different blocks of the district in which Mithaura block takes prominent place where 5 Vantangiya villages are located: Baluahiya, Hathiahwa, 24 Nursery, 27 Nursery and 28 Nursery. The current study deals with the socio-economic status of these villages.

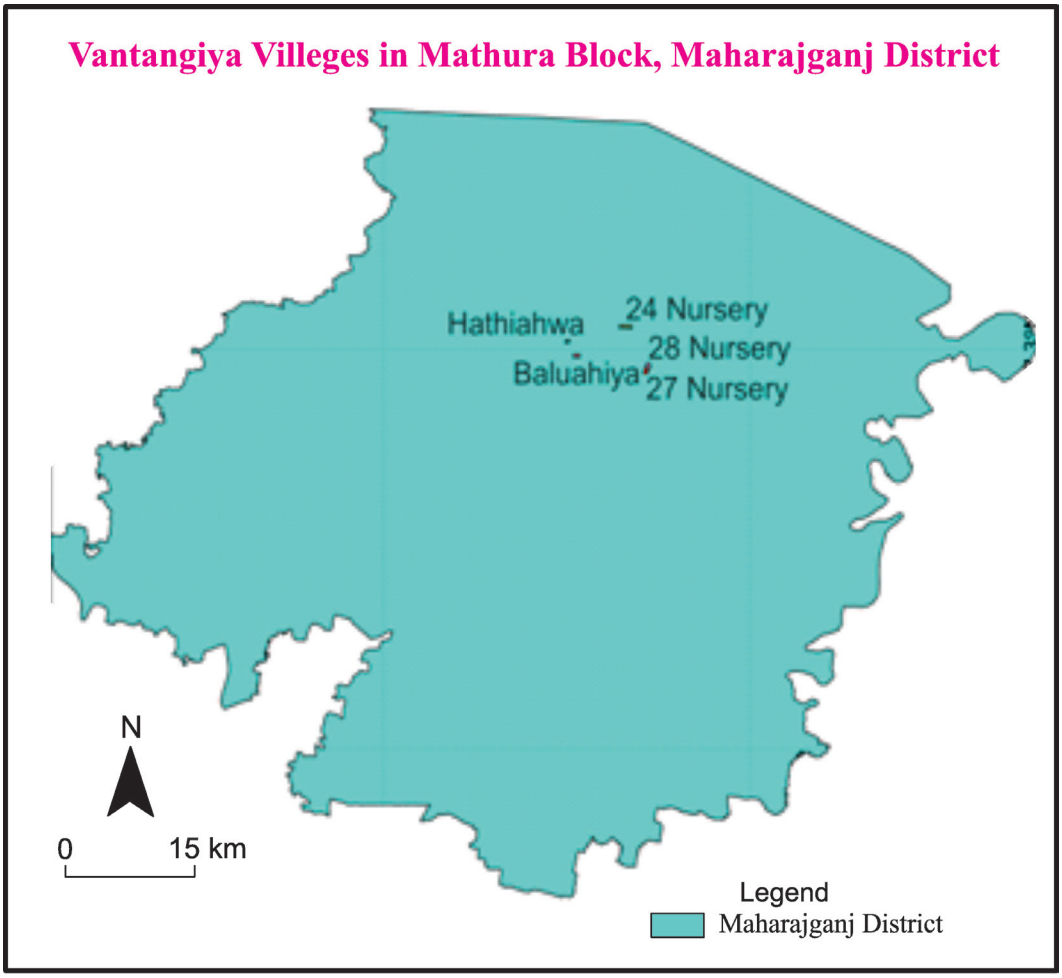
Objective

The main objective of the current study is to analyse the socio-economic status of the Vantangiya community in the Vantangiya villages of Mithaura block of Maharajganj district through the Socio-Economic Index (SEI).

Data Sources and Methodology

The current study is based on quantitative data analysis, and data are collected from primary as well as secondary data sources. This study used questionnaires, interview schedules, focused group discussions, and observation methods in primary sources, whereas in secondary sources, it considered data and documents related to village officials. This study analyzed 100 respondents and selected purposively 20 respondents from each Vantangiya village, Baluahiya, Hathiyhwa, Nursery 24, Nursery 27 and Nursery 28. After collecting the data, the socio-economic status of the Vantangiya community of Vantangiya villages in Mithaura block of Maharajganj district analyzed through the socio-economic index. For this, the current study used the method to calculate the socio-economic index as follows:

Socio-economic Index = {1/2 Social Index} + {1/2 Economic Index}



Vantangiya Villeges in Mathura Block, Maharajganj District
Hathiahwa
24 Nursery
28 Nursery
Baluahiya
27 Nursery

Fig. 1

Socie-Economic Index– The social index is measured by many indicators like health, demographic, and educational factors that impact a person's family or social position. The sum of the health, demographic, and educational indices is thus the social index.

Social Index = (1/3 Health Index) + (1/3 Demographic Index) + (1/3 Educational Index)

Health Index: Health is a major component of social index which affects society directly or indirectly. In this paper access of health and maternal facilities, standard toilet facilities, availability of safe drinking water and electric facilities are included as health indicators (**Table-**1).

Health Index = Actual Value – Minimum value/ Maximum Value – Minimum Value

Table-1: Health-related Variables and Value

Variables	Values
Access Health/ Maternal Care	No = 1, Yes = 2
Standard Toilet Facilities	No Facility/field = 1
Public Toilet = 2	
Pit/ Flush Toilet = 3	
Safe Drinking Water	No Facilitity = 1
Surface Water = 2	
Tube well/ Handpump = 3	
Basic Electric Facility	No = 1, Have = 2

Source: Computed by Authors

Demographic Index: Demography directly affects development of any society. People's marital status and family size are playing a key role to decide their level of socio-economic development (**Table-**2).

Demographic Index = Actual Value–Minimum value/Maximum Value–Minimum Value

Table-2: Demographic Variables and Code

Variables	Values
Age of Marriage	Less than 21(Male) 18 (Female) = 1, 21-25 (Male) 18-21 (Female) =2, Above 25(Male) 21 (Female) = 3
Size of Family	Above 5 members = 1 5 members = 2 4 members = 3 3 members = 4 Less than 3 members = 5

Source: Computed by Authors

Individual Educational Index = Actual Value/ Maximum Value

Education occupies a prominent role in the social index. An educated society achieves new dimensions of socio-economic development (**Table-**3).

Table-3: Educational Category and Code

Category	Code/Values
No Education/ Illiterate	1
Primary Incomplete/ Literate	3
Primary Complete	5
Junior High School	8
High School	10
Secondary	12
Graduation	15
Post Graduation	17
Ph.D/Other Advanced Study	18

Economic Index: The aspects that affect a person's or family's financial situation, such as income, spending, involvement in community events, occupation, and land ownership, have an impact on the economic index (**Table-**4). With the use of the Socio-Economic Index (SEI) measuring formula, the following tables are constructed for the SEI of respondents of the different villages of Vantangiya community in Mithaura Block of Maharajganj district (**Table-**4 and 5).

Economic Index = Actual Value–Minimum Value/ Maximum Value–Minimum Value

Table-4: Economic Variables with their Category and Value Category

Variables	Values
Monthly Income (Expected)	Up to 10000=1
10000-20000 = 2	
Above 20000 = 3	
Expenditure Less than Income	Yes =2, No =1
Participation in Community Events	Yes =2, No =1
Occupation	No Job = 1
Day Labour/ Farmer/Housewife = 2	
Government/ Private Job = 3	
Land Ownership	
(Household)	Up to 1 Bigha = 1
1-3 Bigha = 2	
Above 3 Bigha = 3

Determining Standard Value for Socio-Economic Index

For analysis and comparison, there is a need for a standard value of the Socio-Economic Index (SEI). To do so, I have assumed a standard value for each variable. For example, the values for the "Age of Marriage" variable are 1,2 and 3 representing ages below 21(male) & 18(female), age between 21-25(male) and 18-21(female), and age above 25(male) & 21(female) respectively. Here the standard value for this variable is 2 or the age of marriage between 21-25(male) & 18-21(female). The list of variables and their standard value (**Table-**10) are tabulated below:

Table-10: Variables and Their Standard Value

Variables	Values	Standard Values
Access Health Care/Maternal Care	No = 1, Yes = 2	Yes = 2
Standard Toilet Facilities	No facility/field = 1 Public Toilet = 2 Pit/flush Toilet = 3	Pit/flush Toilet =3

Contd...

Safe Drinking Water	No facilities = 1 Surface water = 2 Tube well/Handpump = 3	Tube well/ Handpump = 3
Basic Electric Facilities	No=1, Yes=2	2
Age of Marriage	Less than 21 years(male) & 18 years(female) = 1 21-25 years(male) & 18-21 years(female) = 2 Above 25 years(male) & 21 years(female) = 3	21-25 years(male) & 18-21 years(female) = 2
Size of Family	Above 5 members = 1 5 members = 2 4 members = 3 3 members = 4 Less than 3 members = 5	4 Members = 3
No Education/Illiterate	1	Secondary = 12
Primary Incomplete /Literate	3	
Primary Complete	5	
Junior High School	8	
High School	10	
Secondary	12	
Graduation	15	
Post Graduation	17	
PhD/Other Advanced studies	18	
Monthly Income (Expected)	Up to 10000=1 10000-20000=2 Above 20000=3	10000-20000 = 2
Expenditure less than income	No =1, Yes = 2	Yes = 2
Participation in Community Events	No =1, Yes = 2	Yes = 2

Contd...

Occupation	No Job = 1 Day Labour/Farmer /Housewife = 2 Government/Private Job=3	Day Labour/ Farmer /Housewife = 2
Land Ownership (Household)	Up to 1 Bigha=1 1-3 Bigha=2 Above 3 Bigha=3	1-3 Bigha = 2

Source: Computed by Authors

By putting the standard values in the Socio-Economic Index (SEI) measuring formula,

I get the standard value for Socio-Economic index (SEI) = ½ (Social Index + Economic Index) = ½ (0.722 + 0.625)

Socio-Economic Index (SEI) = ½ (Social Index + Economic Index)

Standard Value for SEI = 0.674

Determining Mean Value for Socio-Economic Index (SEI) for different Vantangiya Villages of Mithaura block.

With the help of statistical techniques:

(1) Mean value of SEI for Baluahiya village = 0.414
(2) Mean value of SEI for Hathiahwa village = 0.455
(3) Mean value of SEI for 24-Nursery villages = 0.383
(4) Mean value of SEI for 27-Nursery villages = 0.511
(5) Mean value of SEI for 28-Nursery villages = 0.533
(6) Mean value of SEI for all these 5 villages = 0.459

Socio-economic Status of the Baluahiya Villages

The socio-economic status of the Baluahiya village covering the social and economic indicators is not better at all as none (0%) of the respondents reported standard socio-economic status. The mean SEI value for respondents of the Vantangiya community in Mithaura block is 0.459 and only 35% of respondents of this village whose SEI are 0.459 or above. It can easily be predicted that the

maximum of the respondents of the vantangiya community in Baluahiya village are not have better socio-economic status. The basic social and economic facilities and infrastructure are not available in this village.

Socio-economic status of the Hathiahwa Villages

The socio-economic status of the Hathiahwa village covering the social and economic indicators is not good as only 5% of the respondents have standard socio-economic status. The mean SEI value for respondents of the Vantangiya community in Mithaura block is 0.459 and 50% of respondents whose SEI are 0.459 or above. So the socio-economic status of the Hathiahwa village is not as good as required and the basic social and economic facilities and infrastructure are not available.

Socio-economic status of the 24-Nursery Villages

The socio-economic status of the 24-Nursery village covering the social and economic indicators is not good as only 5% of the respondents have standard socio-economic status. The mean SEI value for respondents of the Vantangiya community in Mithaura block is 0.459 and only 15% of respondents whose SEI are 0.459 or above. So the socio-economic status of the 24-Nursery village is not good and the difference between the mean SEI of this village and the individual SEI of the respondents shows the inequality in their socio-economic status.

Socio-economic status of the 27-Nursey Villages

The socio-economic status of the 27-Nursery village covering the social and economic indicators is good as 15% of the respondents have standard socio-economic status. The mean SEI value for respondents of the Vantangiya community in Mithaura block is 0.459 and 50% of respondents whose SEI are 0.459 or above. So the socio-economic status of the 27-Nursery village is comparatively good among vantangiya villages.

Socio-economic status of the 28-Nursery Villages

The socio-economic status of the 28-Nursery village covering the social and economic indicators is good as 10% of the respondents have standard socio-economic status. The mean SEI value for respondents of the Vantangiya community in Mithaura block is 0.459 and 55% of respondents whose SEI are 0.459 or above. So the socio-economic status of the 28-Nursery village is comparatively better among vantangiya villages. The homogeneity in the mean SEI of this village and the individual SEI of the respondents shows equality in their socio-economic status.

Comparison of socio-economic status among Vantangiya villages of Mithaura block

The mean SEI value is 0.459 for the 100 respondents from different villages of the Vantangiya community in the Mithaura block of Maharajganj district. The mean SEI value for respondents of Baluahiya (0.414), Hathiahwa (0.455), 24-Nursery (0.383), 27-Nursery (0.511), and 28-Nursery (0.533) villages is different and this difference in the SEI level indicates that 27-Nursery and 28-Nursery are maintaining better socio-economic status than the other three Vantangiya villages. Comparing with the standard value of SEI (0.674), none of the respondents in the Baluahiya village have standard socio-economic status; only 5% of the respondents in the Hathiahwa and 24-Nursery village have standard socio-economic status; and 15% and 10% of the 27-Nursery and 28-Nursery, respectively.

Conclusion

This comprehensive and comparative study discussed the socio-economic status of the five Vantangiya villages in the Mithaura block of Maharajganj district. A multidimensional socio-economic index is used to measure the socio-economic status of the Vantangiya community. The Socio-Economic index is the aggregate result of the social index and the economic index. The social index is also subdivided into the Health Index, Demographic Index and Educational Index. The study analyzed 100 respondents from different villages of the Vantangiya community and indicates that 27-Nursery and 28-Nursery villages are in better socio-economic condition than the other three. This study also indicates that there is a huge need for basic socio-economic and infrastructural facilities in these Vantangiya villages to uplift the socio-economic status of the people of the Vantangiya community.

ASSESSMENT OF WILDLIFE HABITAT MANAGEMENT IN MUKUNDRA HILLS TIGER RESERVE, RAJASTHAN

Ms. Aayushi Jain and Dr. Ajay Vikram Singh Chandela

Abstract

Many researches have been done from time to time at local and global level in the context of climate change and biodiversity loss, many reports have been published. However, we all can feel these changes around us. We see the increasing environmental pollution around us and its impact on the life on land. This crisis has increased further due to changes in land use pattern in the last few years. With time, the area under forest cover and water bodies is decreasing while the area under man-made landscape is increasing. This destruction of natural habitat has led to greater decline in biodiversity. The 2022 global Living Planet Index shows an average 69% decrease in relative abundance of monitored wildlife populations between 1970 and 2018. Therefore, keeping in mind the need to conserve biodiversity, we should pay attention to the conservation of their natural habitats and saving top predators is essential for natural habitat conservation. Top predators, like tigers play an important role in maintaining the harmony of the planet's ecosystems. By preying on herbivores, tigers help to keep the balance between the prey animals and the forest vegetation which they feed upon. From the world's largest mangrove forests in the Sundarbans, to the snowy mountains in Northeast China and Russia, protecting wild tigers and their natural homes provides benefits for thousands of species and millions of people. (Why Tigers, n.d.) So we need to study their natural habitats, issues and solutions. This paper is based on common issues found in reserved forest areas. For example, it has been almost ten years since Mukundara Hills Tiger Reserve was declared a tiger reserve, but even today human settlements are present here. However, during the survey it was revealed that the residents themselves are not safe here. They also want to go out of these difficult situations and live a safe and healthy life. Apart from this, the context of water, food and safe habitat for wildlife has been discussed in this research paper also. Satellite images and field survey have been used for analysis. This forest area was also inhabited by

wild animals earlier and even at present there has been no significant change in this area. Most of the human settlements here are natural. Only a few road routes have been constructed. These can also be replaced by the Delhi-Mumbai Expressway in the future and made wildlife-friendly. Therefore, this area can be made a safe wildlife habitat. Moreover, the connectivity of Mukundra Hills Tiger Reserve with Bhainsroadgarh Wildlife Sanctuary in the south and Ramgarh Vishdhari Tiger Reserve and Ranthambore Tiger Reserve in the north makes it an excellent habitat for wildlife.

Introduction

In the Era of Machines and Development, many efforts are being made for environmental protection by the United Nations at the global level for the conservation of biodiversity. In this series, in the Conference on Sustainable Development held at Rio de Janerio in the year 2012, SDG goals were proposed by the United Nations. The purpose of which was to present goals globally to deal with the environmental, political and economic challenges faced by all countries of the world. In this series, in September 2015, United Nations Summit on Sustainable Development was organized in New York and the General Assembly adopted the 2030 Agenda for Sustainable Development with 17 SDGs. This research paper is based on one of them, on SDG 15: 'Life on land.' This goal includes study of our planet's ecosystem. As we know, without forest, there is no possibility of sustainable life on earth, but for the protection of forests, the presence of wildlife is also essential. Conservation of both forests and wildlife is essential for a balanced and secure life on earth, as stated as "The real wealth of the nation lies in the resources of the earth – soil, water, forests, minerals, and wildlife (Racgel Carson) If seen in the context of Rajasthan, the number of wild animals like bear, panther and tigers is increasing continuously, and for their protection it is necessary to study the available forest areas, which provide suitable living conditions for the wildlife. Moreover, seeking a favourable habitat for the cheetahs brought to the Kuno National Park in Madhya Pradesh, is also a need of the hour. To fulfill this objective, we need a place which has been preserving wildlife even in ancient times and which has not changed much even today, like Mukundra Hills Tiger Reserve. Although there are some challenges in front of Mukundra Hills Tiger Reserve even today, but their solution can be derived. In this research paper, we will discuss about those challenges and their solutions.

Study Region

Study area of this research work is Mukundra Hills Tiger Reserve, which has considerable diversity in topography, climate, vegetation, water resources etc. It is situated in the extension of Hadoti Plateau and Aravalli in the south-eastern Rajasthan, where Chambal, Bamani, Ahu, Kalisindh etc. rivers give life to land, make the forest flourish and create fertile plains.

Mukundra Hills Tiger Reserve (MHTR) was formed in 2013, which includes the area of Mukundra Hills National Park, Dara Sanctuary, Jawahar Sagar Sanctuary and National Chambal Gharial Sanctuary (from Garadia Mahadev to Jawahar Sagar Dam), which constitutes the core area of the Mukundra Hills Tiger Reserve in the Rajasthan. The tiger reserve is spread over an area of 759.99 square kilometers and is located in Ladpura, Sangod, Ramganjmandi tehsil of Kota district, Jhalarapatan tehsil of Jhalawar district, Talera tehsil of Bundi district and Rawatbhata tehsil of Chittorgarh district in Rajasthan. Jawahar Sagar Sanctuary is located between North Latitude 24°56' to 25°7.5' and East Longitude 75°26.50' to 75°41'. It is located 35 kilometers from Rawatbhata and 75 kilometers from Bundi. It is governed by the Government of Rajasthan Notification No. F 3(5) (13) Rev. 18/73 dated October 9, 1975 was declared as a sanctuary. The Mukundra Hills Tiger Reserve is named after the narrow central range with two continuous flat-topped and almost parallel hills, which is part of the Vindhya Range system, which extends from the Chambal River to Kalisindh and is about 80 kilometers in length and is 2 to 5 kilometers in width.

Objectives

(1) To analyze the problems faced in harmonizing the habitats of all living beings on the Earth as SDG 15.

(2) To study Mukundra Hills Tiger Reserve as suitable wildlife habitat for ever increasing tiger population in Rajasthan.

(3) To evaluate significance of Project Tiger in Rajasthan.

Database and Methodology

This research work is based on both primary and secondary data. The suitability of vegetation, water and habitat in the forest area has been studied with the help of satellite images and for its authentication, the area was surveyed. Satellite images of LANDSAT 8 have been used to analyze the forest area and health of vegetation. NDVI is calculated using Raster Calculator tool. In addition to this field survey was

done through schedule to study the human impact and environmental condition of villages located in Mukundra Hills Tiger Reserve. During this survey, information was obtained from the residents about their lifestyle and their dependence on the forest. Apart from this, their impact on the forest was also analyzed. Some research papers and books related to forest management and biodiversity have been studied. Newspapers have been mainly used as secondary data to get information about positive and negative changes happening in Mukundra Hills Tiger Reserve from time to time. Maps were prepared with the help of open-source software. To create maps of the study area, shapefiles taken from forest department portal- 'rajforest' and 'Survey of India' portal were used.

Factors affecting wildlife habitat in Mukundra Hills Tiger Reserve

Water Resources

Mukundra Hills Tiger Reserve is located in the region of Rajasthan with more than 70 cm of rainfall. The only perennial river of Rajasthan, Chambal, and its tributaries, passes through the Mukundra Hills Tiger Reserve. They provide water to the Mukundra Hills Tiger Reserve for most of the year. The topography of Mukundra Hills Tiger Reserve also ensures the availability of water here. The Vindhyan range extends up to the Mukundra Hills Tiger Reserve, locally called Mukundra Hills, from which the rainwater seeps down and accumulates throughout the year in the foothills and lower areas of the valleys. Apart from this, the Forest Department is also conserving more than 100 natural and artificial water bodies in this region. (**Fig.** 1)

Food and Habitat

70 percent area of Mukundra Hills Tiger Reserve is covered with mixed deciduous forest. Dhok (Button), Khair (Black kutch), Churail (Indian elm), Amaltas (Golden shower), Sal, Gurjan, Palash (Bastard), Arjun, Tendu, Ber, Behda (Beleric Myrobalan), Mahua (Buttercup), Khejdi, Babool, Neem, Banyan, Peepal, Khechda, Khakara, Bamboo, Bilvapatra, Amla and many other species of deciduous forests found here. It provides favorable habitat and sufficient food to the wildlife (**Fig.** 2). Thorny autumn forests are found here, whose dry leaves provide food for herbivore animals chinkara, chital, sambar, nilgai, deer, and langurs even in autumn, which provide ample prey base like wolf, jackal, fox, mongoose, wild cat, civet, porcupine, wild boar, panther and tigers. Thus, there is enough food even for carnivorous animals. From the point of view of natural habitat, the total area

of Mukundra Hills Tiger Reserve is 759.99 square kilometers, out of which 417.17 square kilometers comes under the core area and the rest under the buffer area. Out of the core area, the area of 82 square kilometers is surrounded by wire fencing. The grassland is well developed within this wire fencing and sufficient prey base is also available in it. Apart from this, one enclosure of one hectare has been made in Selzar area of the tiger reserve and another enclosure of 28 hectares has been made in Sawan Bhado area. (Source: Dainik Bhaskar Newspaper, 05.05.2023) In addition to the above, Mukundra Hills Tiger Reserve has a glorious history as an abode of tigers, but now due to changing land use pattern some disparities have arisen in this area which need to be resolved.

Roads and Railways

National Highway 52 and Delhi-Mumbai railway line pass through Mukundra Hills Tiger Reserve for length of about 50 kilometers. The high speed of vehicles and blind turns of the roads have many times led to the death of wildlife. There are 30 villages located in the core and buffer area of Mukundra Hills Tiger Reserve, in which more than 1500 families reside. Although about 200 families have been relocated from here in the last 8 years, but still the residence and farms of the rest of the families are existing in the forest area. These forest dwellers go to the nearest cities only through the forest area to get the goods they need and for employment. It is dangerous for the life of both humans and wilds (**Fig.** 3).

Project Tiger in Rajasthan

The Tiger Project in Rajasthan started in 1973 when Ranthambore was declared as the first Tiger Reserve of Rajasthan in 1973-1974. In the next phase of the Tiger Project, Sariska was declared a Tiger Reserve in the year 1978-79. But even after three decades of the Tiger Project, there was a continuous decline in the number of tigers in Rajasthan. Tigers vanished from Sariska Tiger Reserve in the year 2005 and only 14 tigers were left in Ranthambore Tiger Reserve. But gradually the conditions started improving; the number of tiger reserves was increased, villages were relocated from Ranthambore and Sariska, mining and deforestation were banned and as a result, gradually the number of tigers started increasing in Rajasthan, which can be understood from the following table: At present, there are about 115 tigers present in Rajasthan. With the formation of Mukundra and Ramgarh Vishdhari Tiger Reserves, a natural wildlife corridor has been created for tigers in the south eastern part of Rajasthan. The number of tigers has grown

substantially in Rajasthan. Due to increasing population of Tigers, the tigers have started migrating to nearby forests of Madhya Pradesh and Rajasthan. This depicts the picture of success of the Tiger Project in Rajasthan.

Conclusions

In conclusion we can say that, Mukundra Hills Tiger Reserve has favourable natural conditions for the habitat of wildlife, but due to anthropogenic activities some anomalous conditions have arisen here. For example, on July 15, 2013, a tiger 'Broken Tail' had come from Ranthambore Tiger Reserve towards the Darrah forest area while roaming. But unfortunately, he was crushed to death by the Rajdhani Express on the Delhi-Mumbai rail route. After this, about 6 years later, in the year 2019, the T-98 tiger, leaving Ranthambhore Tiger Reserve and traveling about 150 kilometers, reached the Darrah region of Mukundra Hills Tiger Reserve via Kalisindh river.

This is the second case of moving from one tiger reserve to another through forest area. Therefore, there is a need to improve following conditions as much as possible and make them wildlife friendly. As (1) The villages should be relocated soon (2) The speed of vehicles should be regulated (3) Grasslands should be developed (4) There is uncertainty of rainfall in Rajasthan. Therefore, to deal with such situations, artificial water points should be developed and water availability should be ensured throughout the year using solar pumps as proposed in Ramgarh Vishdhari Tiger Reserve (5) Security walls should be built around the forest area so that wildlife stays away from rail and road routes and human settlements (6) Tiger reserves of south-eastern Rajasthan should be connected with each other by developing wildlife corridors. Although after the declaration of Mukundra Hills Tiger Reserve as such, many efforts are being made by forest department, and central and state government for the development of Mukundra Hills Tiger Reserve. In view of the protection of wildlife, mining work and deforestation has been banned in this area. Grasslands are being developed so that sufficient food is available for herbivorous animals and sufficient prey base can flourish in the forest. Now if there is any threat to wildlife it is from road and rail routes and human settlements. Forest Department. Apart from this, to ensure wildlife conservation in the area, measures have been taken in the Bharatmala Project, under which Delhi-Mumbai Expressway is being constructed. For wildlife conservation an eight-lane soundproof twin tunnel is being constructed. Along with this, the relocation of six villages settled in core area has also been done. (Shah, 2020)

IMPACT OF ROADSIDE FRICTION ON ROAD CAPACITY IN ALIGARH CITY, INDIA

Dr. Fatma Mehar Sultana, Rehma Nooreain and Dr. Naushaba Naseem Ahmed

Abstract

Indian cities are notorious for poor road capacity and the slow average mobility. Aligarh city has massive problem of traffic congestion and inadequate transportation infrastructure as the narrow lanes and roads crisscross the city. Absence of the well-designed junctions, footpaths and cycle tracks makes it difficult for pedestrians, cyclists and vehicles to commute safely. Moreover, the lack of traffic management has led to the usual traffic congestion and frequent road accidents. Inadequate parking space causes traffic jams due to road side unauthorized parking. One of the important reasons for this traffic chaos is that the city has one of the fastest growing populations due to the migration of people from rural areas as well as from other parts of the state and country, mainly for education and employment. It is the 77th most populous city in India. Due to Covid -19 lockdown restrictions much of the ridership in Aligarh city was curbed. Still, not much change was being observed in the side friction and traffic congestion. The busy roads of Aligarh city have emerged as the site of parallel economic structure for the migrants, poor and the marginalized section of the city. In this paper we have done a comparative study of two roads of the busy market areas of the Civil Lines zone of Aligarh city during the Lockdown, following all the protocols. The purpose of the study is to analyze the degree of influence the road side friction has upon the road capacity caused by the road side economy. The paper concludes that the side friction has considerable negative impact on the capacity of roads in Aligarh's market areas.

Introduction

Road transportation system has been playing a vital role in the socio-economic development of cities all over the world. Road traffic in India is marred by poor condition and below par performance. The main focus in the studies regarding speed-flow relationship of road traffic is on geometry, street type and urban environment

of roads. Recently many studies have concluded that in the cities of the developing world there are some activities going on or along the roadsides which influence the capacity of the road network which is known as the side friction (R. Amudapuram et.al, 2016). Road capacity is defined as the maximum sustainable flow rate at which vehicles can be expected to traverse a point or uniform section of a lane or roadway during a given time period under the prevailing roadway traffic and control conditions (IRC, 1990). The condition is getting worse in the cities of developing world where the increasing transport demand is causing the deterioration in the road capacity of the arterial and the local roads, and the inefficient performance of the traffic system (Salini.S et. al., 2014). As per the Indian scenario, the presence of the roadside markets and vendors is a common observation in every city. They attract people to stop by, which reduces the effective road width due to the roadside parking of the vehicles and other parking and un-parking maneuver. Due to lack of the meaningful employment for migrants and unskilled and semiskilled individuals, and the unavailability of the specified area for their informal fringe economic activities; vendors, rag pickers, mechanics etc. are also found to work along the roadside. The presence of road side markets, vendors, food stalls and the lack of pedestrian facilities compel people to walk on or along the road which disturbs the traffic flow. In consequence, traffic flow is considerably interrupted. It diminishes the performance of traffic operations and undermines the capacity and the functional integrity of the road. The road side frictions have negative effect on the road capacity as the width of road decreases and it becomes narrow. Side friction leads to decrease in the speed of vehicles, aids in the delays and becomes a cause of accidents. Literature review reveals that very little work has been done in 'Y' category cities in India like Aligarh till date to measure the impact of roadside friction upon the capacity of urban roads. This study intends to measure the influence of roadside frictions on the capacity of road in Aligarh city during the lockdown period in order to establish that even the regulated opening of the city creates unmanageable side friction reducing the capacity of roads below the base value. The study will be a precursor to the road traffic administration of Aligarh Smart city to find out the ways to regulate the unmanageable urbanization and the exponential motorization.

Study Region

Aligarh has been classified as class Y city (HRA, 2015) and one of the National Priority Cities and potential urban growth centers of India (Report of National Commission on Urbanization, GOI, 1988) located outside the National Capital

Region (in 150 km radius). It is the administrative headquarters of Aligarh district, and lies approximately 130 km south east of the capital, New Delhi. Aligarh Muslim University, the world famous seat of learning, is located here. Besides, it is a hub of a large number of small scales household and cottage industries, some of important large-scale food and agro-based industry, and the brass and lock industries. The decadal population growth rate of the city is 30.40 percent for 2001-11(**Table-**1).

Table-1: Geometric Parameters of the Roads under Study

Road Characteristics		Road	
		Marris Road	Dodhpur Road
Geometric condition	Road Types	Single Carriageway 2 Way	Single Carriageway 2 Way
	Carriageway Width	7 m	7.2 m
	Shoulder Width	2.7	1.1
	Road Alignment	Straight	Straight
	Footpath Width intermittent	2.6 m	2.5 m
	Road length	2.57 km	3.08 km
Environmental condition	Weather Condition	Day/Dry	Day/Dry
	Urban/Suburban	Urban	Urban
	Pavement Condition	Paved/Near to Smooth	Paved/Smooth
Traffic control condition	Nearby Major Intersections	Present	Present
	Traffic Signs	Present	Absent
	Pavement Markings	Present	Absent

Source: Based on Survey, 2021

The annual population growth of the city is reported as 3.16, 2.97, 2.89 and 2.81 percent for 4 consecutive years from 2017 to 2020 respectively. The estimated population of Aligarh city is 1,013,089 in 2021(UN- World Population / prospects). The population density of the city has increased from 14,500 persons per square km in 1971 to 24,573 persons per square km in 2011(excluding the University area). 10 percent of the urban population has spread beyond the city limits and in the towns which are also dependent on this city for their major needs.

The city is also having a high rate of motorization. The growth of road length network is not keeping pace with it.

Objectives

(1) To measure the vehicle composition and traffic flow rate of Marris and Dodhpur roads.

(2) To identify the major sources of side friction on these roads and to estimate the magnitude of side friction.

(3) To calculate the actual capacity of both roads.

(4) To estimate reduction in base capacity of both roads due to the side friction.

Database and Methodology

The present study is based on the primary sources of data generated through the comprehensive field survey, traffic counting (TC) survey, side friction (SF) survey, and geometric survey carried out during year 2021 in the month of April. The secondary data is collected from the Census of India (2011). For determining the influence of road side frictions on the capacity of road, two roads of Aligarh city are selected, with roadside friction activities. These are the Marris road and the Dodhpur Road which are undivided two lane two ways (2/2 UD). The survey was conducted for four hours from 8:00 am to 12:00 pm on these two roads. On each road a 50-meter length is specified for the surveys. In this study the evaluation of traffic flow, roadside friction (Pal and Roy, 2016) and capacity (Indonesian Highway Capacity Manual Urban Roads, 1993) is done according to the techniques mentioned in the sources shown in the parentheses. The traffic count survey was done manually by counting the number of each type of vehicle that had passed the fixed spot on the road in both the directions for every 5 minutes under four categories namely, two wheelers, animal drawn vehicles, three wheelers, cars and heavy vehicles. The vehicles in these categories are heterogeneous in nature. Therefore, for finding the total flow each vehicle type is converted into the homogenous category. Flow is calculated by converting the volume of vehicles per 5 minutes into the equivalent PCU (passenger car unit) as per IRC code. The peak hour factor (PHF) is calculated for finding the peak flow of an hour by the formula given by (HCM, 1965) as:

$$PHF = v \frac{60}{av} \Big/ 12xv \frac{5}{av}$$

Average volume during the peak 60 minute period v_av^60 is divided by twelve times to get the average volume during the peak 5 minute's period v_av^5. For the side friction survey a section of 50-meter length on both roads was delineated and width was measured with the help of a measuring tape. On these two sections of the both roads the survey was done to count the number of pedestrian /hour walking, vehicles parked or stopped on their way for a while /hour/width, number of vendors standing/hour/width, number of stray animals moving/hour/width, number of beggars present along the road/hour/width. Pedestrian is considered unit of friction. Impact of side friction included the physical dimension of the side friction as well its position on the carriage way. Area effect of an element of friction is considered as the ratio of projected area of a particular friction to pedestrian and expressed as area ratio (AR). Positional disturbance effect of an element is calculated as the ratio of distance of particular midpoint of strip from edge of carriageway on which friction element is positioned to midpoint of the edge strip named as distance ratio (DR). Weight factor for each element is determined by summing up area ratio and distance ratio. After assigning weight these frequencies are converted into a single unit of roadside friction index (RSVI). To plot the side friction frequency graph all categories of side friction frequencies are summed up and then average frequency per five minutes is calculated for the whole study duration. The geometric survey was done to measure the width of the carriageway, and its edge strips and the middle strip. These capacity parameters have helped in finding the capacity of two roads. Capacity is F calculated as follows.

$$C = C_0 \times FW \times FKS \times FSD \times FSF \times FCS$$

Whereas:

C_0 = Base Capacity

SF = Curb and shoulder adjustment factor

FW = Carriageway width adjustment factor

FSF= Curb and shoulder adjustment factor

FKS = A directional split adjustment factor

FCS = Side friction adjustment factor

FSD = City size adjustment factor

The actual capacity is determined by multiplying the base capacity with all the adjustment factors as mentioned above. The capacity is dependent upon the

geometry of road (the width of road, shoulder width, city size, and median width), side friction activities and the city size. So the values of different adjustment factors have been taken from (Indonesian Highway Capacity Manual Urban Road, 1993). Actual capacity of both roads is estimated by calculating percentage of base capacity reduction.

Results and Discussion

Composition of Vehicles of Roads, (2021)

Traffic Composition is shown in Fig 2 and it is clearly indicated, at Marris Road the vehicle composition is found to be as; two wheelers' 61 percent (bicycle 2.99%, motorcycle and scooter 58.543%), animal drawn vehicle 0.5 percent, car 20 percent, e-rickshaw 15 percent, bus 2 percent and others 2.07 percent. On Marris Road two wheelers and cars have the greatest contribution in traffic flow. However, at Dodhpur it is found that two wheelers constituted 62 percent (bicycle 3.08%, motorcycle and scooters 59.35%), car 14.24 percent, e-rickshaw 18.08 percent and others 5 percent (animal drawn vehicles, truck, van, tractor etc.) of the total traffic. Two wheelers and e rickshaws are the most ubiquitous vehicles here. (Fig 1)

Traffic Flow Analysis

The traffic flow is greater at Marris Road as compared to at Dodhpur road. At Marris Road peak hour volume is 2269.353 pcu/hour observed in between 9.40am-10.40am. Marris road's connectivity with the Center Point, a major marketing area of Aligarh city, Ramghat road and railway junction is the main cause of greater traffic flow. At Dodhpur road peak hour volume is found to be 1803.6 pcu/hour between 9.20 am-10.20 am and it is mainly due to the vendors and regular shops attracting the major share of the traffic flow.

Composition of Road Side Friction

Fig 2 and 3 show, at Marris Road main components of the roadside friction are roadside parking, vendors, food stalls, squatters etc. occupying the footpath and allowing less space for pedestrian's movement resulted into the movement of pedestrians on the road or along the road causing hindrance to the flow. There are three schools located along this road but because of COVID 19 their contribution in hindering the flow is negligible due to the online. In normal time these schools cause considerable road side frictions.

Fig. 1

At Dodhpur road the roadside friction is mainly due to the presence of vendors compelling pedestrian movement along the road. The roadside parking has emerged as the second biggest factor causing the side friction on Dodhpur road as here no official legalized parking space is found. Squatter, begging and dumping also act as other sources of friction for the traffic flow on this road. Due to increasing rate of in migration and lack of suitable employment more people are turning up to the road side informal economy as vendors. Due to absence of the decent public transportation and traffic infrastructure, private ownership of vehicle is increasing but absence of proper parking facilities it is creating more road side frictions. Road side friction is greater at Dodhpur road as compared to at Marris Road. At Dodhpur road the peak hour for the roadside friction is between 9.45 am to 10.45 am. The frequency of roadside friction count is found as 110-116 per hour. Roadside vendors, Restaurants, and Market attracted the flow during this time. At Marris Road the frequency of roadside friction is found to increase and decrease alternately and being maximum between 10.35 am-11.35 am.

The frequency of friction is found to be 80-75 per hour as it is the time when restaurants, shops, banks, offices etc. located here and the vendors attract the flow causing road side parking and pedestrians' movement on the road. It is evident that the overall roadside friction during peak hour is less at Marris Road as compared to Dodhpur road. During the study it was found that the edge of the roads experienced more side friction as compared to the middle part of the road. Therefore, for the better results the sections of both roads under the study were divided into two portions, one meter edge strips on both sides of the carriage way and the remaining 5 meter and 5.2-meter middle strip for Marris and Dodhpur road respectively. **Table-**2, 3 and 4 shows a detailed analysis of the weighted factors assigned to the different types of side friction element found along the edge strips and the middle strips of Marris Road and Dodhpur road. di is distance of ith friction element from carriageway edge, A_i projected area of ith friction element, AR is area ratio, DR is distance ratio and PA is projected area. These calculated values are used to develop the road side friction index (RSFI) (**Fig.** 2 and 3). It is clearly indicated in **Table-**3 that RSFI is greater at Dodhpur road (3937) as compared to that of Marris Road (2564.4). Therefore, we can deduce that the encroachment of road by the road side friction activities is greater at Dodhpur road as compared to that of Marris Road.

Capacity Analysis

Adjustment Factors of Parameters of Capacity is given by (IHCM1993) and Actual Calculated capacity of Marris and Dodhpur Road (2021). It is clearly revealed that the actual capacity of Marris Road being 2680.05 pcu/ hour is greater than the actual capacity of Dodhpur road which is 2297.47pcu/hour. The base capacity at Marris Road is decreased from 2900pcu/hour to 2680.05 pcu/ hour and at Dodhpur road from 2900pcu/hour to 2297.24 pcu/hour due to high and very high levels of side friction respectively. **Table-**5 shows the reduction in capacity of both roads due to side friction. This finding is in conformity to other studies conducted in India and Indonesia (Sulistyono et.al. 2018). These studies highlight a reduction of capacity to the extent of 10-60 % due to different elements of side friction (**Table-**5).

Table-5: Capacity Reduction in Study Region

Location	RSFI	Base Capacity	Actual Capacity	% Reduction in Capacity due to side friction	% Reduction in Capacity including side curb
Marris Road	3679.2	2900	2680.05	10.76%	19.63%
Dodhpur Road	4960	2900	2297.47	20.78%	20.78%

Source: Based on Survey, 2021

Conclusion

The study reveals that the private vehicles have greater contribution in traffic flow (80%) on both the roads as compared to the public transport. The activities which cause main roadside friction (94%) at Marris Road is mainly by the roadside parking and the pedestrian movement making. The activities along Dodhpur road are mainly pedestrian movement roadside parking and vendors, comprising overall 99 percent of the total side friction activities. RSFI calculated to show the magnitude of roadside friction is found to be greater at Dodhpur road (4960) as compare to at Marris road (3679.2). The percentage reduction of the base capacity only due to side friction is greater at Dodhpur road as compared to at Marris Road, thus, it concludes that the roadside frictions have a greater impact on the capacity of road. The availability of the legalized parking area on both the roads, specified area for the hawkers and vendors, and footpath for pedestrian movement can drastically reduce the frequency of roadside friction. Installation of the intelligent traffic monitoring system, regulation on loading and unloading of the passengers by e-rickshaws, redesigning and readjustment of roads, construction of a roundabout at Dodhpur intersection are some of the actions which are required to be implemented on the priority basis.

SPATIO-TEMPORAL DYNAMICS OF FLOOD SEVERITY USING MULTI-TEMPORAL SATELLITE DATA: A CASE STUDY OF KOSI FLOODS

Dr. Supriya and Dr. Shipra Soni

Abstract

Flood is a natural phenomenon and frequent disaster that occurs in the North Bihar Plain and causes damage to life and property almost every year. The main cause of floods in Bihar is usually known by people to be the shifting and slitting of rivers. The continuous silting has made the rivers shallow and losing their depth, so they are unable to face the forceful rain during the monsoons, which in turn results in breaking their banks and spreading water on the plains. Which is further reflected in the distinctive events like river course change and river capture in the flood plains of Bihar. Since floods increase each year, resulting in loss of life, property, and farm output, it is possible to use a generic approach as an estimate of flood damage. To mitigate flooding, spatial analysis is of paramount importance for the timescale and temporal characteristics of flood-affected areas. The Kosi River is one of the highly vulnerable to flood and is known for its frequent flooding, river course changes, and river-capturing events. The Kosi region faced a devastating flood on August 18, 2008, due to a breech at Kusaha village, which caused not even loss of property and lives but the change in the river course itself. Satellite imagining technology emerged as a powerful tool for the analysis of inundation areas and flood severity in the Kosi flood-prone basin during breech and flood. In order to better understand seasonal and yearly variations in the number of floods and to facilitate emergency response, this research provides an algorithm for mapping precipitation and flood inundation. Hence, the present study made an attempt to analyze the changes in rainfall and severity of flood using multi-spectral-temporal satellite data of the Kosi River basin for the 2008 Flood, Pre-flood (2007) and post-flood (2009) situations. The paper aims to describe thresholding and unsupervised classification methods to determine inundated areas, changes in persistent rainfall, and rising Kosi River water levels.

Introduction

Floods are the most widespread natural hazard that account for most damage and loss of life. They also can have serious secondary impacts on the economy and agriculture. Geographers have studied the complexity of such flood hazards for many years and have made significant contribution to their understanding. Flood is defined as any flow that exceeds the bank full capacity of a stream or channel and flows out of the floodplain, greater than bank full discharge. According to the World Meteorological Organization, a flood as a "(1) Rise, usually brief, in the water level in the stream to a peak from which the water recedes at a slower rate. (2) Relatively high flow as measured stage height or discharge. (3) Rising tide" (WMO, 1992). The magnitude of the floods and their probability of occurrence are strongly connected, although these relationships are regionally specific and depend on climatic conditions and characteristics of river catchment. On 18th August 2008, the eastern embankment of Kosi River was breached near Kusaha village, Nepal, about 12 km upstream of the barrage. At the time of breach, the river flow was below average, considering the same time-period in different years. The water inundated the adjoining villages of Kusha and Haripur (Nepal) immediately and reached Bhimnagar, Birpur (India) within a few hours. In Birpur, flood water rose alarmingly to a height of 5–6 ft within a short time after the breach. Subsequently, the flood water spread over a great extent covering Supaul, Saharsa, Madhepura, Araria and Purnea districts, causing severe damage to life and property.

In fact, after the 18th August breach, the Kosi River has altogether taken a new course, that of the 1930s, as reported by residents near Muraliganj. The Kosi River system is a monsoon-fed river system which has a long history of devastating floods in its lower catchment. After the 1954 floods in Nepal and Bihar, the flow of the Kosi River has been regulated by an embankment, constructed in 1963, on both sides of the river. The 2008 flood happened after breach of a levee on 18 August 2008 near Kusaha in Nepal, 12 km upstream on the eastern embankment of the river. The avulsion abandoned the current river course and the water followed an ancient channel midway through the alluvial fan. This led to inundation of a huge area, devastating the lives of millions of people (UNICEF Report 2008). Kosi River is considered as 'Sorrow of Bihar' since a long time due to its recurring and substantial flooding and repeated change in its course over the years. The change of river course has well documented in British rule. The river has changed its course in a westerly direction and it has laterally moved nearly 150 kilometers (Gole and Chitale, 1966; Wells and Dorr, 1987).

The movement of the river has not been gradual but of avulsive nature (sudden change in river course) originating from a nodal point (Wells and Dorr, 1987). The average avulsion frequency has been recorded as 24 years which is among the lowest in the world compared to 1400 years for the Mississippi river (Slingerland and Smith, 2004). Several paleochannels on the satellite image of the Kosi basin testify the migratory behavior of the river (**Fig. 1**). The river is typically braided in nature and has formed a very large alluvial fan due to a large sediment supply from the Himalaya and a generally aggregational regime. Further complications arise due to (a) very high rainfall in the catchment (1200- 2000 mm in most parts; Sinha and Friend, 1994), and (b) high seismicity in the hinterland causing landslides and large sediment production which eventually fill up the basin. The initial flood control schemes were introduced during late 19th century which included construction of marginal embankments, high dam at upstream section, river training in lower reaches and a series of barrages and canals. However, no consensus was reached and no definitive action could be taken until 1953. A very severe flood in 1953–54 and the subsequent social and political pressure led to the first serious attempts towards flood control the Kosi basin and the formulation of the 'Kosi project' in 1954. This project was primarily aimed at flood control and to provide irrigation for increasing agricultural productivity. The project started in 1959 and the river was diverted through the barrage in 1963. The embankments on both sides have been designed to protect nearly three thousand square kilometers of land in north Bihar and Nepal. Although the embankments have checked the lateral movements of the Kosi, the flooding problem continues in the Kosi basin and the objectives predicted in the Kosi project have been only partially met. Several large floods and frequent breaches in the embankments have continued to occur in the region. In addition, several adverse effects of the Kosi project have been noted viz. drainage congestion and water logging rise of river bed level, and reduction in crop productivity due to reduced silt flux on the floodplains (Ghani, 2001). In the view of above mention facts the present paper attempts to analyze the severity of 2008 Kosi flood and the spatio-temporal dynamics of flood severity of Kosi floods with pre (2007) and post (2009) flooding situation using multi temporal satellite data. It also examine the effectiveness of precipitation.

Study Region

The Himalayan terrain, the Kosi river is formed by the confluence of seven smaller streams, viz. Indravati, Sun Kosi, Tama Kosi, Likhu Kosi, Dudh Kosi, Arun Kosi and Tamar Kosi at different places in China, Tibet and Nepal,

before its entry into the Indian state of Bihar In India, the Kosi river merges with the mighty Ganges near Kursela village, Katihar District, Bihar. Kamla, Baghmati (Kareh) and Budhi Gandak are the major tributaries of Kosi in India, besides many minor tributaries like Bhutahi Balan. The mountain-fed Kosi River has a total basin area of nearly 84,739 sq.km of which only 11,842 sq.km lie within Indian Territory and spans a total length of 730 km from its source to the confluence with the Ganga at Baltara. (Gole and Chitale, 1966; Sinha and Friend, 1994). The Tibetan region of the Kosi basin comprises 22% of the total drainage area and is characterized by high elevation and flat plateau on the leeward side of the Himalaya with many glaciers and glacier lakes (Bajracharya et al., 2007). About 40% of the drainage area of the Kosi basin lies in the Nepal Himalaya and is characterized by alpine and mountainous areas.

The alluvial part of the Kosi basin in the Bihar plains in India comprises 38% of the total drainage area and comprises low elevation and flat plains with high population density (**Fig.** 1). The climate of this region is monsoon sub-tropical. The Kosi region or Kosi division is an administrative unit of Bihar comprising three districts i.e. Saharsa, Supaul and Madhepura. The present study is confined to assess the severity of deluge falling under this region. NASA's Shuttle Radar Topography Mission (SRTM) DEM (Digital Elevation Model) data shows that the topography of Kosi region ranges from 30 meters near the confluence in Ganga River to 89 meters near Kosi Barrage at Bihar – Nepal border.

Objectives

(1) To study interpolated precipitation map of three years i.e. 2007, 2008 and 2009 to understand the rainfall pattern of the study area.

(2) To assess side by side comparison of precipitation and flood intensity and to extract numerical values of the extent of flood in all three study years.

Database and Methodology

Climatic Research Unit (CRU) gridded Time Series data is used for preparing precipitation map. Flood inundation layer for each year was generated using ISRO's multi-temporal satellite datasets (2007 to 2009) comprising of either IRS WiFS (188 meters) / IRS P6 AWiFS (56 meters) / Radarsat ScanSAR Wide / Narrow (100 meters & 50 meters) acquired during the flood season of that particular calendar year are used. The Raster data of flood inundation was downloaded using compatible software and with the help of Kosi region vector data study area masked out.

Fig. 1

The flood inundation layer for each year was delineated from satellite data by applying suitable classification technique. The precipitation map was prepared using the interpolation techniques in ArcMAP. Inverse Distance Weighted (IDW) was used to determine the temporal intensity of rainfall in Kosi region. Identification of flood prone area was done using the raster file in Global Mapper by using creating area feature using equal value tool in layer menu. The flood area vector layers were created and then smoothened using smoothing tool. The flood inundated area for each year was calculated and numerical values were noted in sq.km.

Results and Discussion

One of the main purposes of this study was to acquire interpolated precipitation map to understand spatio-temporal pattern of rainfall in Kosi region. The outcome of the rainfall pattern could be well understood (**Fig.** 1, 2 and 3 and **Table-**1, 2, 3 and 4.

The flood inundation map for all three years was prepared using ISRO's Bhuvan raster data. These raster data contained ISRO's multi satellite sensors ranging from IRS series (WiFS, P6 AWiFS) to microwave satellite data from Radarsat satellites (ScanSAR Wide/ Narrow). The water levels observed at different gauge stations were closely monitored during floods and attempts were made to program the satellite data during peak/near peak positions. The next step was to create flood inundation layer using image processing classification algorithms, water layer was extracted from the satellite data and integrated with the pre-flood river and water bodies layer to derive flood inundation layer. Finally annual flood layer was created. The flood inundation layers generated for different flood waves in a calendar year were integrated to generate the maximum flood inundation extent observed in that year (Fig 1, 2 and 3). The second objective of this paper was to show the flood intensity and extract numerical values to know the extent of flood in study years (2007, 2008 and 2009). This can be analyzed in data obtained through raster data processing obtained from ISRO (**Table-**2, 3 and 4) while the manifestation of deluge could be observed in above processed maps. The processed data of 2007, a year before the famous 2008 flood shows the maximum extent of inundated area of Kosi region was nearly 922 sq kms which was approximately 15.6 percent of the total area under Kosi region. In 2008, the inundated area nearly doubled and in about 1752 sq kms. It accounts around thirty percent of the total Kosi region area. Finally in 2009 which was the post flood year, there was a drastic fall in flood inundation in Kosi region. The flood inundated area reduced to barely 228 sq kms which was less than four percent of total area of the Kosi region. It is also a major fact that 2009 was an El Niño year and it had lesser annual precipitation in comparison of both 2007 and 2008 as well.

Conclusion

In this paper, we have determined the variation of intensity in rainfall with the help of CRU grided time series data, and the spatio-temporal variation is represented

in the rainfall map prepared through ArcMap IDW tools. The result clearly reveals that in 2008, the upper plain of the Kosi River received a higher amount of average mean rainfall (1800mm) than in the post- and pre-flooding years. It was caused by the breach in the upper Kosi basin of Bihar, which helped raise the water level in the entire area and cause flooding. The study also reveals the changes in flood-prone areas with the help of the extraction of flood-inundated areas in Kosi River for the same time period through the analysis of multi-satellite data acquired from different sensors ranging from IRS series (WiFS, P6 AWiFS) to microwave satellite data and Radarsat satellites (Scan SAR Wide/Narrow) data and further converted in pixels to area in Global Mapper by using the Create Area feature. It reveals that approximately 30 percent of the total area was inundated due to floods in 2008; therefore, only 15.52 percent of the area in 2007 and 3.84 percent of the area in 2009 were submerged. It has clearly represented through the flood severity maps that in 2008, the eastward part of the study area was highly inundated, which was changed after 2008 flooding through the westward due to the main channel shifting towards the west and creating a very high flood hazard risk zone. Hence, the combined use of multi-temporal imagery and metrological data analysis achieves the objective of preparing flood severity maps for the study area. The spatio-temporal precipitation data, flood data, and processed maps can be used for the purposes of identification of annual precipitation effectiveness and rainfall pattern in Kosi region threshold area, identification of constantly flooded areas, regulate land use in the inundated areas and spotting safer flood relief shelters. In order to raise awareness among researchers and the scientific community, the possible importance of this research is to include these efforts as part of general flood management measures that do not include structural measures aimed at reducing short-term and longer-term damage. It is also a simple and cost-effective methodology for flood management and mitigation.

GENDERED PERSPECTIVES OF MIGRATION TO GUJARAT: BEHIND THE NUMBERS

Dr. Harpreet Singh and Ms. Gauri Hanspal

Abstract

Migration is a complex phenomenon with profound implications for individuals and regions. This study explores migration to the state of Gujarat, India, shedding light on the gendered perspectives often overlooked in migration studies. Utilizing data from the Census of India 2011, the research analyzes the volume and patterns of in-migration, emphasizing the role of gender in shaping the demographic landscape of Gujarat. The introduction delineates the significance of migration, differentiating between internal and international migration based on administrative boundaries. It underscores the selectivity inherent in migration processes, driven by diverse factors such as age, marital status, education, gender, socio-economic status, and housing situation. Gujarat's status as a counter-magnet for individuals from economically constrained states is highlighted, with a focus on the megacity of Surat and other districts attracting migrants for varied opportunities. Maharashtra, Uttar Pradesh, and Rajasthan emerge as significant contributors to Gujarat's in-migrant population, playing pivotal roles in shaping migration dynamics. The study aims to uncover the nuanced narrative beneath migration statistics, emphasizing the often-overlooked role of gender. The spatial distribution of male and female in-migrants across different districts of Gujarat further reveals distinct patterns. Key findings highlight a notable gender imbalance in the in-migrant population, with higher female representation, particularly in rural areas. Maharashtra, Uttar Pradesh, and Rajasthan dominate in contributing in-migrants, emphasizing their pivotal roles. The study concludes by emphasizing the importance of considering gender-specific migration dynamics for informed policy interventions that address the diverse needs of both male and female migrants. This research contributes valuable insights for policymakers and scholars seeking a comprehensive understanding of migration dynamics, particularly the gendered perspectives, in the vibrant state of Gujarat.

Introduction

The movement of people within the boundaries of a country, is classified as internal migration whereas the process of movement of people away from national border, is called international migration(Rahul, 2022). The nature of migration process is selective. The selectivity is due to the differences between the individuals aspirations belonging to different groups. The most important differences are related to age, marital status, level of education, gender, socio-economic status, and housing situation. In case of migration selectivity is not only age based but also a gender based specific process(Khan et al., 2016). The role of gender, often relegated to the periphery in migration studies, is a crucial lens through which we can gain a deeper understanding of the social fabric woven by those who choose Gujarat as their destination. Gujarat, a crucible of cultural diversity and economic vibrancy, has become a magnet for individuals seeking opportunities, employment, and a new way of life. It has been reported in many studies that Gujarat is becoming the counter-magnet for the megacity like Mumbai, large number of migrants from the different states, like Rajasthan and Madhya Pradesh, Maharashtra, Chhattisgarh, Uttar Pradesh, Jharkhand, Bihar etc. where economic opportunities are rather limited (Shah and Dhak 2014) are attracted towards Gujarat. Also, the intra-state migration from less to more developed regions increased significantly as a result of increased connectivity and infrastructure within the state (Hirway et al., 2014). According to the census data on migration 2011, nearer to the half of the population of big cities composed of migrants including both the migrants from within the state and outside the state. Surat has the highest percentage of the internal migrants including both migrants from other states and from within the states. Ahmedabad is also one of the important city which attracts migrants. The major migrants sending states are Rajasthan, Uttar Pradesh and Maharashtra. The main reasons of migration that mentioned in the census are work employment and movement due to marriage (Half of the People in Gujarat's Big Cities Are Migrants | Ahmedabad News - Times of India, n.d.). Though there are large number of micro studies focusing on migration in Gujarat but less focus is on the gender-based migration study.

Objectives

The primary objective of this research is to unravel the often-overlooked gendered dimensions within the migration patterns to Gujarat. By delving into the dynamics of population movement, the study aims to shed light on how

gender influences and shapes the intricate narratives of migration. The study also intends to get information about the spatial analysis of migration across different districts in Gujarat.

Study Region

Gujarat is a state in India located on the western coast along the Arabian Sea. Gujarat is surrounded by the Indian states of Rajasthan to the north, Madhya Pradesh to the east, and Maharashtra to the southeast. It also shares international border with Pakistan in the northwest. Gujarat encircles the territory of Daman and Diu along with the Arabian Sea and shares a short portion of its southeast border with the Indian union territory of Dadra and Nagar Haveli. Gujarat has a 992-mile (1,596-kilometer) coastline. Gujarat is the ninth-most populous state, with a population of 60,439,692. The number of males is 31,491,260 and females is 28,948,432 according to the 2011 census data. The population density is 308 persons per square kilometre (800 persons/sq mi), lower than other Indian states. As per the census of 2011, the state has a sex ratio of 918 females for every 1000 males, one of the lowest (ranked 24) among the 29 states in India. In Gujarat, about three-fifths of the population lives in rural areas, however as urban areas have expanded, so the percentage of people living in rural areas has declined. The main concentration of population is in the eastern part of the state, in the plains surrounding the cities of Ahmadabad, Kheda, Vadodara, Surat, and Valsad; the region is both agriculturally productive and highly industrialized. There are also other population centres on the Kathiawar Peninsula, including on the southern shore between Mangrol and Mahuva, in the inland near Rajkot, and along the Gulf of Kachchh near Jamnagar. The population distribution rapidly declines towards the mountainous areas of eastern Gujarat and the northwest Kachchh district. The literacy rate of Gujarat is 79.31%. Gujarati is the official and primary language (Gujarat State Portal | All About Gujarat | Gujarat at a Glance, n.d.).

Database and Methodology

The present study is descriptive in nature. The study is based on the secondary sources of data. The census of India is the major source of information. The analysis of patterns of migration is based on the secondary source of data that is Census of India 2011. The data has been taken from the Migration Table (D series) of the census data and the place of last residence is taken into consideration for migration. Data based on the streams of migration like urban, rural and duration of migration have been carried out. The analysis and graphical representation of data has been done in excel.

Results and Discussions

Gender Disparity in the Volume of In-migrants to Gujarat

According to 2011 census, in total there are about 26.89 million migrants recorded in Gujarat as per their place of the last residence which forms nearly 45 percent of the total population of Gujarat. This all owing to the infrastructural and industrial development in Gujarat. Out of the total enumerated In-migrants i.e., 26,898,286 male in-migrants are 9,994,352 and female in-migrants are 16,903,934 females. In term of percentage males are 37 percent whereas females are 63 percent, suggesting a notable gender imbalance with a higher count of females. The In-migrants coming to rural and urban areas of Gujarat are 49 percent and 51 percent of the total In-migrants. Delving into the urban-rural breakdown, the total In-migrants enumerated in the rural area of Gujarat is 13,098,287, with 3,140,671 males and 9,957,616 females. In rural areas, the gender disparity leans towards females. In term of percentage the females are 76 percent of total migrants coming to rural areas. Conversely, the urban population of 13,799,999 exhibits a different pattern, with 6,853,681 males and 6,946,318 females. This indicates that urban areas attract a higher number of males. Males are dominated in all three basic industries like construction, textile and diamond industry the ratio of female workers is very less in these sectors (Hirway et al., 2014). These observations could be indicative of complex migration patterns, where males may be more inclined to migrate to urban centers for employment or other opportunities, leaving a higher proportion of females in rural settings.

The comprehensive analysis of in-migration patterns to the state of Gujarat delineates intriguing dynamics across various States and Union Territories (States/UTs). At the forefront, Maharashtra emerges as the primary contributor with 24.82% of the total in-migrant reported in the state of Gujarat, a substantial figure amounting to 971,975 individuals. Following closely by the state of Uttar Pradesh which contributes significantly with 23.73% in-migrants. The volume wise number is 929,411. According to a repot whenever a migrant from Uttar Pradesh visited their homes they bring their relative along with them to work in the textile industry the next important industry is diamond industry. Rajasthan, with 19.09%, constitutes another substantial share, which is 747,445 individuals enumerated in Gujarat. Migrants from the tribal areas of Rajasthan like Dungarpur and Banswara migrate to the state of Gujarat for work in constructional sites. Together, these three states form a significant portion, totaling 67.64% of the overall in-migrant population, indicating their pivotal roles as preferred origin place for those seeking

new opportunities, employment, and improved livelihoods. The main industries providing employment to migrants in Gujarat are construction industry, brick kiln industry, diamond cutting and polishing industry, textiles and power looms, and garments, engineering and electrical industries, domestic work, salt pan workers and other informal sectors(42 Lakh Migrants Have Made Gujarat Their Home | Ahmedabad News - Times of India, n.d.). Beyond these leading contributors, Bihar, Madhya Pradesh, Odisha, and West Bengal also play crucial roles in the intricate tapestry of in-migration, contributing to the overall diversity of population movement within the region. The other states are Bihar, Madhya Pradesh and Odisha. The odhiya workers are mainly engaged in the Surat power loom industries (Hirway et al., 2014). The complexity of these migration patterns underscores the interplay of diverse factors such as economic prospects, urbanization trends, and regional developmental disparities (**Fig.** 1 and **Table-**1).

Table-1: Gujarat: Percentage of In-migrants to Gujarat, 2011

State/UT's	Males	Females
Total In-Migrants	55.93	44.07
Maharashtra	46.34	53.66
Uttar Pradesh	64.61	35.39
Rajasthan	48.71	51.29
Bihar	70.28	29.72
Madhya Pradesh	49.37	50.63
Odisha	76.01	23.99
West Bengal	61.07	38.93
Jharkhand	77.33	22.67
Andhra Pradesh	50.91	49.09
Kerala	51.93	48.07
Remaining States/UT's	49.82	50.18

Source: Census of India, 2001

The analsis of in-migration patterns from States and Union Territories (States/UTs) reveals intriguing gender dynamics, showcasing variations in the male-to-female ratio among in-migrants. On an overall scale, in-migrants exhibit a slightly higher representation of males at 55.93%, compared to 44.07% females. Notably, Maharashtra demonstrates a gender distribution leaning toward females,

with 53.66%, while Uttar Pradesh sees a higher male representation at 64.61%. Rajasthan maintains a relatively balanced ratio, with 51.29% females. Bihar presents a significant gender disparity, with 70.28% males dominating the in-migrant population. Madhya Pradesh shows a nearly equal distribution, with 50.63% females. Odisha exhibits a substantial male majority at 76.01%, contrasting sharply with Jharkhand, where females constitute 77.33% of the in-migrants. West Bengal displays a more balanced representation, with 38.93% females. Andhra Pradesh, Kerala, and the remaining States/UTs exhibit fairly equal gender distribution patterns, with minor variations. This nuanced analysis underscores the importance of considering gender-specific patterns in understanding in-migration dynamics, potentially influencing policy considerations related to healthcare, education, and social services catering to the diverse needs of both male and female in-migrants (**Table-**2).

The analysis of In-migration across all the districts of Gujarat provides insights into the gender distribution among in-migrants, revealing distinct patterns in various locales. From the **Table-**2, it is clearly seen that there is dominance of male in-migrants in case of more urbanized districts like Surat, Ahmedabad, and the main reason behind this is the availability of male oriented wok and employment. Surat, with a total of 10,60,934 in-migrants, exhibits a male-dominated influx with 63.99%, whereas females constitute 36.01% of the migrant population. In contrast, Ahmadabad sees a more balanced gender distribution, with 52.38% males and 47.62% females among the total 3,79,097 in-migrants. Vadodara displays a slight female majority at 51.73% among its 1,33,451 in-migrants. Valsad follows a similar trend, with 55.49% males and 44.51% females among its 1,33,422 in-migrants. "Golden Corridor" is the industrialized center of state formed by the districts of Valsad and Vadodara. These are the fastest growing cities in Gujarat, one can see the boom in constructional activities there, lot of construction happening in the real estate & major infrastructure projects are being undertaken by private as well as public sectors, the people migrated here to work in the constructional sites, these districts are also known for their textile and the diamond industry. The women workers didn't get jobs in the large and medium diamond polishing units. They tend to work in the low-profile jobs, in constructional works, cotton fields etc. In the less urbanized area we find the dominance of females the major reason behind this is the marriages (Hirway et al., 2014). Banas Kantha and Sabar Kantha, however, portray significant gender disparities, with a notably higher percentage of females at 76.39% and 75.9%, respectively. The highest gap between male and

Table-2: Gujarat: Spatial Pattern of In-migrants to Gujarat, 2011

female migrants recorded in the districts of Dohad, Patan and Banas kantha. These all are the bordering districts and share close connection with the bordering states and linked by the social and cultural ties. Bharuch, Jamnagar, and Navsari maintain a more balanced gender distribution, reflecting the diverse patterns in migration. Bhavnagar, on the other hand, stands out with a substantial male majority at 66.71%. Districts like Dohad and Patan exhibit pronounced gender imbalances, with 84.32% and 78.77% females among their respective in-migrant populations.

Conclusion

In conclusion, the study illuminates the intricate dynamics of migration to Gujarat, with a specific focus on gendered perspectives. The state's economic vibrancy and cultural diversity have attracted a significant influx of migrants, both from within and outside its borders. The migration patterns highlight Gujarat as a counter-magnet for individuals from states with limited economic opportunities. Gender disparities in migration are evident, with a higher representation of females in the overall In-migrant population. Urban areas, particularly districts like Surat, witness a male-dominated influx due to the availability of male-oriented employment. Conversely, less urbanized districts, especially those bordering other states, exhibit a notable dominance of females, often driven by marriage-related migration. Maharashtra, Uttar Pradesh, and Rajasthan emerge as primary contributors to Gujarat's In-migrant population, collectively playing a pivotal role in shaping migration dynamics. Further research and targeted studies on gender-specific migration dynamics can provide deeper insights for more refined policy interventions in the future.

BLOCK LEVEL DISPARITY OF HEALTH CARE FACILITY AND THE PERFORMANCE OF RURAL HEALTH CARE OF NORTH BENGAL, INDIA

Dr. Biswajit Das, Shantanu Paul, Goutam Mandal and Lamhu Dolma Tamang

Abstract

Health is one of the determining factors that can expedite the process of social and economic development of the nation. The general health condition of the people of an area is indicative of the quality of the health care facilities available in that area. The present study strives to analyse different dimensions of health care facilities to find out the status of health care system of North Bengal, India and assess the performance of the rural health care units. To do so, Health Care Facility Index (HCFI) has been measured to appraise the overall health care condition of North Bengal. The analysis estimates the efficiency of the healthcare system at block level using data of census 2011, district statistical hand book 2014 and State Bureau of Health Intelligence, Govt. of WB 2016-2017. The English Bazar block of Malda district has shown the height HCFI and Goalpokhar-I of North Dinajpur shows the minimum level of HCFI. There is a substantial difference in performance between these two blocks, resulting from inadequate utilization of available health care resources. The study also identifies complementarities of private health care resources and the role of other factors, such as Health Care Institution Population Ratio (HCIPR), Bed Population Ratio (BPR), Doctor Population Ratio (DPR), Doctor Health Care Institution Ratio (DHCIR) and Bed Health Care Institution Ratio (BHCIR). The results suggest a need for better utilization of budgetary resources to increase health infrastructure and manpower to improve the quality of rural healthcare through training and better management of resources in order to overall performance of the rural healthcare systems in North Bengal.

Introduction

"Health is a condition of complete physical, mental, and social well-being, not only the absence of sickness or disability," (World Health Organization, 1948). This definition explains the significance of health, which is seen as a fundamental human right and a key indication of human growth. In recent years, there has been

renewed emphasis on efficiency in resource utilization in the healthcare sector. A number of studies have focused on the overall performance of the healthcare system and its impact on health outcomes (Murray & Frenk 1999; World Health Organization [WHO] 2000). Some notable studies, for instance, have concentrated on hospitals, nursing homes, Health Maintenance Organizations (HMOs) and district health authorities (Wang, (1999); Sankar & Kathuria 2004). India had made remarkable progress in the field of health. The first important initiative was made in 1943, by Health Survey and Development Committee Report and known as Bhore Committee (KPMG and ASSOCHAM, 2011). It was a detailed plan for healthcare in the country. The initiatives' list included the adoption of a National Health Policy in 1983, the 73rd and 74th Constitutional Amendments devolving power to local institutions in 1992, the National Nutrition Policy in 1993, the National Policy on Indian System of Medicine and Homeopathy and Drug Policy in 2002, introduction of a first health insurance schemes for poor people in 2003 and the inclusion of health in the Common Minimum Program of Government in 2004.

In order to improve the National Health System of India it is therefore necessary to evaluate and assess the health services in terms of quantity, quality, cost and sustainability (Capolongo et al. 2016b, 2015a). Moreover, most important aspects is the adjusting service delivery structures to meet the health needs of the population in terms of quantities and modalities of networked, affordable and sustainable evidence based services (Buffoli et al. 2015) and modernizing outdated structures. Currently India has 0.6 beds every 1,000 inhabitants. This scenario is worsened by the scarcity of architectures for health and support staff that leads to have 50% of beds in the public health sector and 30% in the private one not utilized totally. Nevertheless, the situation has, however, slightly improved by NRHM, founded by 85% the Union and the remaining 15% by the states, which aims to bring its action in rural areas strategic, engaging more than 800,000 workers paid according to the performances Capolongo S, B. M. (2015a). The public health is mainly guaranteed by primary levels, with differences between rural and urban areas; in urban areas there is a double level system: a Basic Health Post for few thousand inhabitants and a Health Centre Urban, or Urban Family Welfare Centre, for 100,000 people attached with a general hospital. Instead, in rural areas there is a triple level system: a Sub-Centre for 5,000 inhabitants manages by two professionals (a man and a woman); a Primary Health Care Centre for 30,000 people with medical and paramedical staffs; a Primary Hospital with 30 beds per 100,000 inhabitants and some basic specializations (WHO, India 2012). The last cases include primary care services, which mean that they are specialized, mainly, in vaccinations,

prevention of malnutrition, pregnancies, postnatal care and treatment of common diseases. The public health infrastructure in West Bengal area is wide covering even in the remotest villages. As HOPE Annual NGO Report reported, there are 9 Medical College Hospitals, 16 District Hospitals, 45 Sub divisional Hospitals, 346 Community Health Centers, 922 Primary Health Centers and 10.356 Sub-Centers across West Bengal (HOPE, 2014). More recent data, by Ministry of Health and Family Welfare, estimate that there is a rise in health Infrastructure: 13,186 Sub-Centers, 2,166 Primary Health Center and 541 Community Health Center. However, the level of welfare seems to be very poor in the entire region (Ministry of Health and Family Welfare, 2015). The healthcare system has a primary healthcare network, a secondary care system comprising district and sub□divisional hospitals and tertiary hospitals providing specialty and super specialty care. Each of the nineteen districts is coordinated by a Chief Medical Officer of Health (CMOH), together with Deputy and Assistant CMOHs, whose responsibility is to manage the primary health care and to ensure the effective implementation of the various medical, health and family welfare programs (Rebecchi, 2018).

The secondary level hospitals are managed by medically trained Superintendents, who directly report to the CMOH, all the useful information and take part into a hospital management committee. In addition, there is the Block Medical Officer, who is responsible for providing services, monitoring and supervising the primary health centres and health program implementation. The third level hospital is referred by two levels before; its specialist care needs to be identified and then patients can be directed to specialized departments. West Bengal Health Service provides the health care professionals for the state wide infrastructure, while Medical Education Service employs teachers at the training institutions (Office of the Registrar General and Census Commissioner, 2011). In general, the community based primary healthcare services have been formulated with the objective of bringing an overall improvement in the urban health scenario in West Bengal; 62 urban local bodies have completed training of honorary health workers. Ministry of Health and Family Welfare of the Government of West Bengal is responsible for healthcare administration in the region. The program budget for two years (2020-2021) was around ₹11,280 crore (US$1.4 billion, Ministry of Health &Family Welfare, West Bengal, 2022). The current study aims to examine the health-care facility system in the North Bengal districts of West Bengal on a block wise to see the disparity among the block in terms of health care facility and their performance.

Objectives

(1) To determine the block wise disparities in health care facilities in all Districts of North Bengal.

(2) To assess the block wise performance of Rural Health Care Facilities of North Bengal.

Study Region

North Bengal is a region located in the northern part of the Indian state of West Bengal. It is renowned for its breath-taking natural beauty, varied flora and wildlife, and extensive cultural history. The region is bounded by the lofty Eastern Himalayas in the north, and it shares its borders with countries like Nepal, Bhutan, and Bangladesh. The study area extends from approximately 24°40'20"N to 27°13'N latitude and 87°45'50"E to 89°53'E longitude. North Bengal consists of eight districts, namely Cooch Behar, Alipurduar, Jalpaiguri, Kalimpong, Darjeeling, Uttar Dinajpur, Dakshin Dinajpur, and Malda. It is characterized by a division into two distinct geographical zones. The northern part is classified as the Sub-Himalayan Zone, while the southern part is composed of sediment and debris brought by rivers descending from the slopes of the Himalayas. Consequently, except for the northern fringe, the entire region consists of plains. Numerous rivers, including the Teesta, Torsha, Jaldhaka, Raidak, Sankosh, Mahananda, Punarbhaba, Atrai, and Kulik, drain the study area. The climate in the study area is characterized by hot, humid conditions and heavy rainfall, although the northern hilly areas experience a cooler climate. The region is also home to diverse species of fauna and flora. This region is characterized by its diverse physical and socio-cultural aspects, displaying notable variations in economic and human development across the districts. It covers an area of 21,855 square kilometres, which accounts for 24.62% of the state's geographical area. According to the 2011 census total population of the region were 17291050, which were 18.83% of the state's total population, with a higher concentration of Scheduled Caste (SC) and Scheduled Tribe (ST) populations, as well as a significant influx of immigrants. The region has a total of 462 healthcare institutions with 13949 beds and 1628 registered doctor's facilities only, which is not sufficient to cater to the present population.

Materials and Methods

The present study is fully based on secondary database, gleaned from District level Census report, 2011, State Bureau of Health Intelligence,

Govt. of WB 2016-2017 and District Statistical Handbooks, 2014 of eight districts i.e., Alipurduar, Cooch Behar, Darjeeling, Jalpaiguri, Kalimpong, Malda, North and South Dinajpur of North Bengal. In order to compute the Health Care Facility Index, block level total population, numbers of health care institutions (both public and private), total number of beds and total number of doctors have been collected for total 69 blocks of North Bengal region. All the Hospitals including Rural Hospitals, Block Primary Health Centres (BPHC), Primary Health Centres (PHC), other clinical Departments of Govt. of West Bengal including State Govt. Undertakings, Local Bodies, and Govt. of India including Central Govt. undertaking, N.G.O. / Private Bodies (Nursing Homes) have been considered as Health Care Institutions (HCI). Total number of beds and total number of Doctors of each C. D. Blocks have been collected from District Statistical Handbooks of Eight Selected District, 2014 (Census, 2011; District Statistical Handbooks, 2014). The Health Care Facility Index (HCFI) is a combination of five selected dimensions. These dimensions have been calculated on the basis of above-mentioned data for each block it includes – Health Care Institution Population Ratio (HCIPR), Bed Population Ratio (BPR), Doctor Population Ratio (DPR), Doctor Health Care Institution Ratio (DHCIR) and Bed Health Care Institution Ratio (BHCIR). The HCIPR dimension/indicator is used to find out the number of health care institutions to serve one lakh population in the region. Bed Population Ratio or BPR is used to measure the number of beds available per 10000 populations in the study area. On the other hand, the Doctor Population Ratio or DPR helps to indicate the number of doctors per one lakh population in the region. The DHCIR dimension/indicator is used to find out the number of doctors per health care institution and the last dimension i.e., Bed Health Care Institution Ratio or BHCIR is used to measure the number of beds per health care institution in the study area. The following formulas have been incorporated to measure the above-mentioned dimensions/indicators for health care facility system-

$$HCIPR = \frac{Health\,Care\,Institution\,(HCI) \times 1,00,000}{Total\,Population} \tag{1}$$

$$BPR = \frac{Number\,of\,\,Beds\,in\,HCI \times 10,000}{Total\,Population} \tag{2}$$

$$DPR = \frac{Number\,of\,\,Doctors\,in\,HCI \times 1,00,000}{Total\,Population} \tag{3}$$

$$DHCIR = \frac{Number\ of\ Doctors\ in\ HCIs}{Number\ of\ HCIs} \quad (4)$$

$$BHCIR = \frac{Number\ of\ Beds\ in\ HCIs}{Number\ of\ HCIs} \quad (5)$$

After calculating the ratio of the five variables the values of each indicator are first normalized to an index value of 0 to 1, using Dimension Index formula. With the actual value for a given block, and the overall maximum and minimum, the dimension (indices) value for each metric is calculated as:

$$HFCI = \frac{A_i - m_i}{M_i - m_i}$$

Where,

d_i = Dimension index of ith dimension,

A_i = Actual Value of ith dimension,

M_i = Maximum value of ith dimension and

m_i = Minimum value of ith dimension.

Now, in order to measure the Health Care Facility Index for each block of North Bengal the composite index has been calculated using the five mentioned indicators. The formula used in the UNDP Goal Post technique uses minimum and maximum values that have been specified. However, in this technique, we have taken into account the observed minimum and maximum values for each dimension. According to Goel and Sharma (2017), the dimension's value (*di*) is between *0* and *1*. The success of the C.D. Blocks/Municipal Corporation is predicted to be higher in the i^{th} dimension by a high dimensional value (*di*). Considering all the five dimensions, i^{th} C. D. Block can be represented by a point (d_1, d_2, d_3) in three-dimensional Cartesian space like $0 \leq d_1, d_2, d_3 \leq 1$. In the three-dimensional Cartesian space, the point '*0*' would indicate the worst condition whereas '*1*' would indicate the ideal or perfect condition. HCFI is measured by the normalized inverse Euclidean distance of the point (d_1, d_2, d_3) from the best or perfect point.

$$HFCI = 1 - \sqrt{\frac{(1-d_1)^2 + (1-d_2)^2 + (1-d_3)^2 \ldots}{5}}$$

The value of HCFI ranges from '*0*' to '*1*'. The value '0' indicates the worst health care facilities system and '*1*' indicates the Perfect health care facilities. On the basis of the HCFI values, the C. D. Blocks of North Bengal region are classified into three categories. The range $0.5<HCFI\leq1$ indicates 'High' or 'Very Good' health care facility system; $0.2<HCFI\leq0.5$ indicates 'Moderate' health care facility system and $0<HCFI\leq0.2$ 'Low' or 'Poor' health quality facility system.

Result and Discussion

Health Care Institution Population Ratio (HCIPR): The population serviced by a single healthcare facility in the research area is determined using this dimension. In this dimension, Matigara C.D. Block of Darjeeling District is in the best position, while Goalpokhar-I of North Dinajpur District is in the worst. Bed Population Ratio (BPR): The bed population ratio is used to calculate how many beds are available for every 10,000 people. In North Bengal region, the greatest BPR is found in the Kurseong block of Darjeeling District, while the lowest BPR is observed in Goalpokhar-I of North Dinajpur District (**Table-**1).

Table-1: Health Care Facility Dimensions of North Bengal

Dimensions	Goalposts of the Dimensions			
	Maximum Value		Minimum Value	
Health Care Institution Population Ratio (HCIPR)	10.17	Matigara	0.61	Goalpokhar I
Bed Population Ratio (BPR)	40.50	Kurseong	1.23	Goalpokhar I
Doctor Population Ratio (DPR)	55.61	English Bazar	0.99	Itahar
Doctor Health Care Institution Ratio (DHCIR)	9.54	English Bazar	0.25	Rangli Rangliot
Bed Health Care Institution Ratio (BHCIR)	78.25	Darjeeling Pulbazar	8.00	Tufanganj II

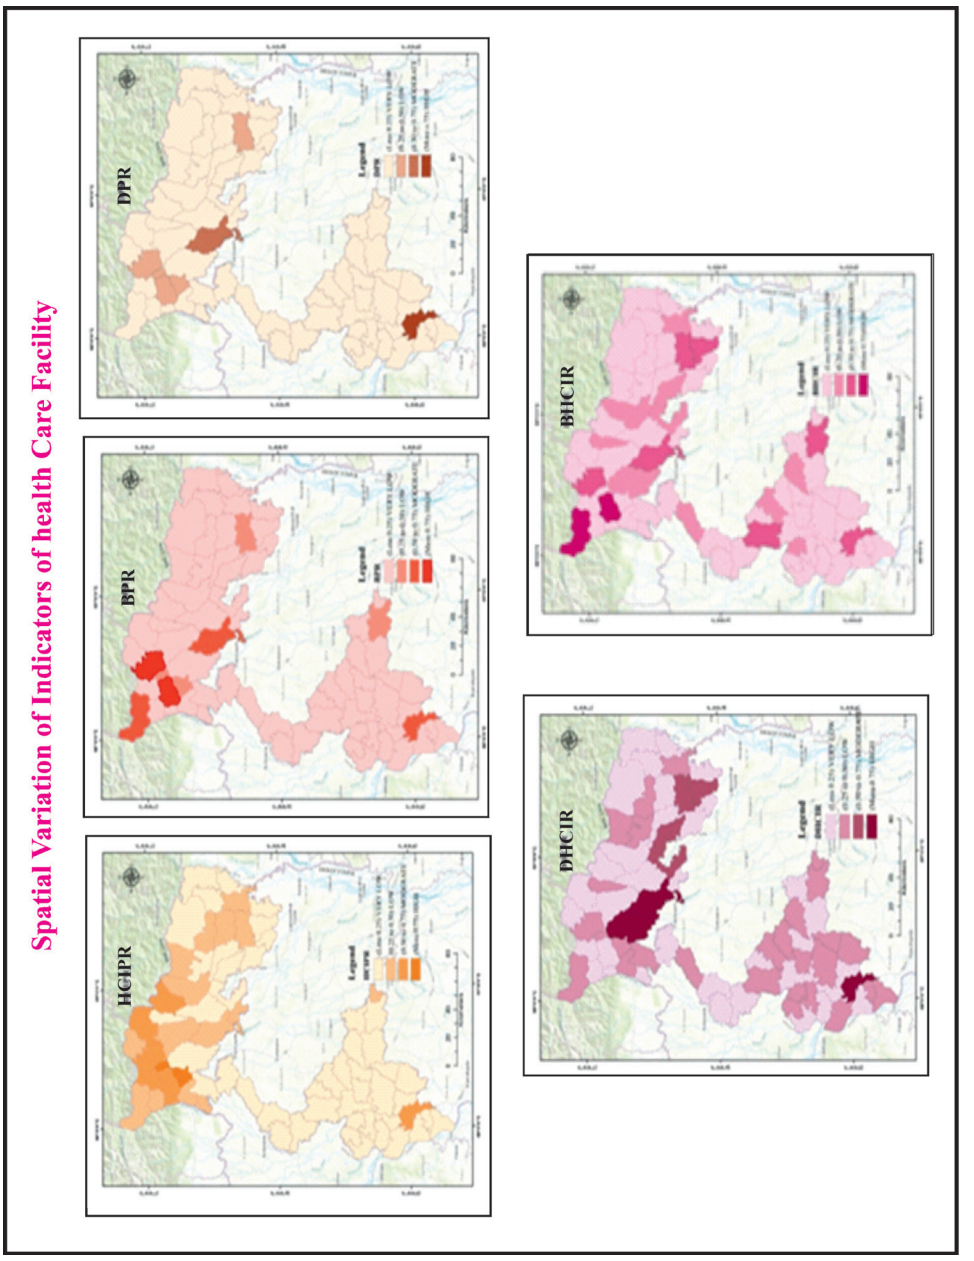
(2) Computed by the Authors

Doctor Population Ratio: The number of doctors per lakh of people in the study region is indicated by this dimension. According to the Planning Commission of India's 2011 report, the doctor population ratio should be 1 doctor per 1000 people (**Fig.** 1). However, in North Bengal as a whole, none of the blocks can reach this crucial DPR threshold. The lowest DPR is found in Itahar block of



Spatial Variation of Indicators of health Care Facility
DPR
BPR
HGIPR
BHCIR
DHCIR

Fig. 1

North Dinajpur District, while the highest DPR is observed in English Bazar block of Maldah District (**Fig.** 1).

Doctor Health Care Institution Ratio: To determine the number of doctors per healthcare facility in the study area, this dimension is used. After analysing the dataset, it is observed that Rangli Rangliot block of Darjeeling District has the poorest DHICR conditions in the entire North Bengal, whereas English Bazar C.D. block of Maldah District has the maximum number of doctors per institution.

Bed Health Care Institution Ratio: In the study area, this dimension is used to calculate the average number of beds per healthcare facility. The more beds in a hospital means the better for the local people and shows the better healthcare facilities. Tufanganj II in Cooch Behar District has the minimum number of beds per institution whereas Pulbazar in Darjeeling District has the maximum number of beds per institution.

Health Care Institution Population Ratio: This indicates Health Care Institution Population Ratio which is one of the five main indicators of the Health Care Index. Based on the ratio of the HCIPR it is observed that Matigara block of Darjeeling district is in the top with index value 1 and Goalpokhar-I of North Dinajpur district has the lowest index value of 0. Based on the index values all the blocks have been categorized in four parts. Very low having the index value of 0 to 0.25, low 0.25 to 0.50, moderate 0.50 to 0.75 and last one is high more than 0.75 value. The map revels out of the total 68 blocks 46 blocks are comes under very low category which is 67.64 percent of the total block of the entire region all the blocks of Uttar Dinajpur and Dakshin Dinajpur. Low HCIPR has been recorded in 15 blocks out of 69 and it consists of 22.06 percent. Rest 7 blocks has been recorded as moderate HCIPR which comprise 10.29 percent of the total blocks and out of the 7 blocks 5 are from Darjeeling district which shows that Darjeeling district has the good health care institution as per their total population. High HCIPR is recorded in Matigara block which is again in the Darjeeling District. So, the map indicates that with in the north Bengal part out of the 8 district only Darjeeling district has the proper population and health care Institution ration, the main reason behind is that the biggest city of the north Bengal Siliguri. Siliguri has a quit large number of the private health care institution as the population is high of the city and the hinterland of the city also huge. There is few private super-speciality Hospital also functioning.

Bed Population Ratio: The bed population ratio is used to calculate how many beds are available for every 10,000 people. In North Bengal region, the greatest

BPR in the Kurseong Block of Darjeeling District, while the lowest BPR is observed in Goalpokhar-I block of the North Dinajpur District. The BPR ratio has been normalized based on the dimension index prescribed by UN in the HDI index. All the dimension index values of the BPR is categorized in four parts. Very low index value having less than 0.25, low (0.25 to 0.50), Moderate (0.50 to 0.75) and High more than 0.75 index value. The maps revels that out of the 68 blocks of North Bengal 61 come under very low BPR index which comprises 89.70 percent of the total blocks. Rest 10 percent are from the three different categories. Balurghat block of South Dinajpur, Cooch Behar- I block of Cooch Behar District and Matigara block of Darjeeling district shows low BPR index which comprises 4.41 percent of the total number of the blocks. Moderate BPR index has been found English Bazar block of Malda District, Jalpaiguri Sadar of Jalpaiguri District and Pulbazar block of Darjeeling district. All the six blocks are very close to their district town and some blocks surrounded the district town because of that the BPR index is much higher from the other blocks. Kalimpong Block of newly formed Kalimpong district and Kurseong block of Darjeeling district has the highest value in terms of the BPR index and both fall under the high BPR.

Doctor Population Ratio: The number of doctors per lakh of people in the study region is indicated by this dimension. According to the Planning Commission of India's 2011 report, the doctor population ratio should be 1 doctor per 1000 people. However, in North Bengal as a whole, none of the blocks can reach this crucial BPR threshold. The highest DPR in North Dinajpur District is in Itahar block, while the lowest DPR is in English Bazar in Malda District. From the map of DPR it is observed that 62 blocks out of 69 blocks of North Bengal is under very low (<0.25) category which is comprise 91.17 percent of the total blocks. Only four blocks fall under low (0.25-0.50) category. Jalpaiguri Sadar block of Jalpaiguri district comes under moderate DPR and English Bazar block of Malda district has the high DPR in the entire North Bengal which shows the actual condition of the health care facility.

Doctor Health Care Institution Ratio: To determine the number of doctors per healthcare facility in the study area, this dimension is used. After analysing the dataset, we have discovered that Rangli Rangliot in Darjeeling District has the poorest conditions in North Bengal, whereas English Bazar C.D. Block in Maldah District has the maximum number of doctors per institution. DHCIR ratio again used for the dimension reduction and the values of the dimension index has been categorized in four categories similar to the other dimension as very low, low, moderate and high with the same value rage of the index value to compare with the other indicators and

based on the dimension index value the map has 0 been prepared. Bed Health Care Institution Ratio (BHCIR): In the study area, this dimension is used to calculate the average number of beds per healthcare facility. The more beds a hospital has, the better off the local healthcare facilities are. Tufanganj II in Cooch Behar District has the lowest Bed per health care institution while Pulbazar in Darjeeling District has the highest beds per health care institution (**Fig.** 2).

The map revels that 35 blocks out of the 69 blocks of North Bengal have fall under the category of very low index (<0.25) which indicates 51.47 percent. 27 blocks out of the 68 blocks of the North Bengal are comes under the low (0.25-0.50) category as per the dimension index which comprise 39.70 percent and Moderate DHCIR is observed only in four blocks and all the four blocks are from Cooch Behar District. High (>0.75) DHCIR has been observed only in the rest 3 blocks out of the three 2 from Jalpaiguri District and one from Malda District. From the calculated ratio of the bed per health care also go through the process of the dimension reduction using the dimension index to compare with the other dimension of the health care facilities and the dimension index has been categorized in to the four category, very low (<0.25), low (0.25-0.50), moderate (0.5-0.75) and high (>0.75). Best on the dimension index value the map has been prepared. From the map it is observed that very low index has been found among 50 blocks out of the 69 blocks which comprises 73.53 percent of the blocks. Ten blocks out of 68 have fall under low BHCIR index which comprise 14.70 percent of the total blocks. Moderate BHCIR index is observed in the 8 blocks and only Pulbazar block of Darjeeling district has the highest number of beds per health care institution The above map (**Fig.** 2) indicates the healthcare facility of North Bengal. Similar to the other indices health care facility also categorised into four categories based on the index value which various from 0 to 1. Out of 69 blocks 52 blocks have shown the very low health care facility (less than 0.25) which is 75.36 percent of the total blocks of North Bengal. After calculating the district level health care as a whole it shows the worse condition in Malda and Uttar Dinajpur district are really in a very poor condition followed by the Dakshin Dinajpur and Darjeeling district has the better health care facility among the eight districts of North Bengal followed by Jalpaiguri and Cooch Behar. Low health care facility (0.25 to 0.50) has been observed among the 15 blocks out of 69 which comprises 21.73 percent of overall blocks. Out of the 15 blocks 5 blocks from Cooch Behar which is one third of the total, 3 block from Darjeeling, 2 each from Alipurduar and Dakshin Dinajpur. There is not a single block from Malda district in the low health care facility.

Only 3 blocks out of the 69 blocks of North Bengal are fall under the moderate health care facilities (0.50 to 0.75) which comprises 4.34 percent. These three blocks are from three districts, Kalimpong I (0.54) block from Kalimpong district, Jalpaiguri Sadar Block (0.59) of Jalpaiguri district and English Bazar (0.65) of Malda District are under this category. There is no single block has found with high health care facility with more than 0.75 index value which show the real face of the health care facility of the region (**Table-**2).

Performance of Rural Health Care Units

There are several ways for the assessment of the performance of the health care facilities but in the study simply few parameters have been taken into consideration which is given by the government in their report. For assessing the health care facility here Bed Turn over rate, Bed Occupancy Rate, Average length of stay in hospital, outpatient per day, percentage of deliveries to admission, percentage of emergency admission, percentage of imaging and electro medical test, percentage of laboratory test, and percentage of patient referred to the other hospital these

nine parameters has been taken into consideration. The information related to the performance of rural health care facilities have stated. Bed Turn Over rate (BTR) is maximum in Kaliachak-III (690.2) block of Malda District and Minimum in Rangli Rangliot Block (13.9) in Darjeeling District which indicates the number of patients treated per bed in the specific year (2016-2017) is maximum in Kaliachak-III as compare to the other block of North Bengal. The Bed Turnover Rate is a measure of productivity of Hospital beds. Out of the eight districts of North Bengal, Malda (318.65) is in the 1st rank in BTR followed by Jalpaiguri (168.66) and North Dinajpur (157.42) and lowest BTR is observed by the Kalimpong district (20.63) as Kalimpong is a newly formed district with low population and a smaller number of rural hospital and other health care facilities. Hospital Bed Occupancy Rate means the number of beds occupied for the treatment of the patient divided by the total number of beds over a specific year multiplied by 100. So, in terms of the BOR Rajganj block (460.5) of Jalpaiguri district is in the first rank followed by Nagrakata (445.5) of same district, Kaliachak-III (267.1) and Manikchak (243.1) of Malda district which indicates the patients pressure is very high in these blocks whereas Tapan (6.1), and Banshihari (8.9) block of South Dinajpur show the very low Bed Occupancy Rate as the health care facility is not good of these block so they prefer to go other hospital and the number of bed and hospital in this block also very few in number.

Average length of stay in hospital is another important parameter to assess the performance of health care facility. Average length of stay is mainly depended on the facility and care provided by the health care unit like number of beds, availability of doctors and admission facility and more over to deal with little complicated illness. Average length of stay is maximum in Falakata block (5.7) of Alipurduar district followed by Kalimpong-I and Gorubathan block of Kalimpong district and minimum length of stay in hospital has been observed in Harirampur block (0.2) of South Dinajpur. Percentage of the patient taken admission of delivery is one om the other important parameters of the study. It is observed that Kaliachak-I block of Malda district has the highest percentage of admission related to delivery (47.2%) followed by Chopra (43.9%), Raiganj (41.50%) block of North Dinajpur district (Appendix-3). Although the health care facility of these blocks are not good as these blocks fall under very low health care facility (**Fig.** 2) but due to population pressure the admission percentage is high. On the other hand, Kalimpong-II and Garubathan block has the lowest percentage of admission related to delivery. District wise Malda is in the height rank followed by North Dinajpur main reason behind it

as per the 2011 census birth rate and growth rate of population in high in these two districts of North Bengal. Similarly in terms of the emergency admission in health centre is maximum in these two districts. Karandighi block of North Dinajpur is high in terms of emergency admission in hospital followed by Harischandrapur-I and Raiganj block and minimum percentage of emergency admission has reported in Madarihat block (0.1%) followed by Cooch Behar-I block. Percentage of Imaging and Electro Medical tests are very low in all the blocks of North Bengal, in Alipurduar district only Falakata has reported 0.6% of imaging and eletro medical test and rest other blocks hospital do not have this kind of facilities. Similarly in Cooch Behar, North Dinajpur and South Dinajpur district reported one hospital each with this kind of facility. So the study shows that imaging and electro medical test is not much available in the rural hospital of north Bengal for this service people has to depend on the district of subdivisional hospital. Percentage of Laboratory test also shows the similar type of result but as compare to the imaging and electro medical tests laboratory test is quite higher. Percentage of laboratory test is maximum in Madarihat block of Alipurduar district as Madarihat block hospital is the only hospital in the entire block so the pressure is huge and on the other hand Cooch Behar-II block is nearer to the district hospital so most of the people goes to district hospital than the rural block hospital so it recorded the minimum laboratory test and there are so many blocks shows zero value which mean the imaging and laboratory test facility is not there in those blocks. Percentage of patient refer to the other hospital to discharge patient indicates that height refer percentage is found in Kalimpong district followed by Alipurduar district and lowest refer rate is observed in Malda district. Kalimpong -II and Garubathan has the maximum percentage of refer to the other hospital, the main reason to refer the patient is lack of medical facility in these blocks as per the health care facility map (map3) shows that both the block fall under the very poor category in terms of health care facility.

Conclusion

This paper has attempted to show the health facilities and challenges in North Bengal where the problem of providing effective health care services to the majority of its citizens has become an impossible task. Rural health services which form the backbone of public health system, is lacking in basic infrastructure, staff and essential medicines. The sufficient manpower is an important prerequisite for the efficient functioning of the Rural Health Infrastructure. Health indicators are very poor and the poor face financial ruin if visited by a serious health event. India is committed to the goal ‘health for all’ and in the last four decades, a wide network

of primary health centres and sub-centres has been created. Yet most of the states including West Bengal are far away from this goal. One of the fundamental metrics for assessing a society's well-being is the availability of health care. The health care system in North Bengal has been evaluated in this study by measuring several aspects of healthcare services. Each Block's Health Care Facility Index (HCFI) rating reflects the state of the healthcare facilities there as well as their location within the district. The average HCFI score for North Bengal is 0.19, which suggests that the majority of Districts have modest to subpar health care services. The HCFI of North Bengal, on the other hand, has a standard deviation value of 0.14, indicating that all Districts have moderately good health care services. Among all districts of North Bengal, the mean value is highest in Bed Health Care Institution Ratio, 23.38 whereas Health Care Institution Population Ratio and Doctor Health Care Institution Ratio is lowest like 2.81 and 2.87.

The number of beds in health care institutions per 10000 populations is not better numbered in all districts of North Bengal with 7.32/10000 population. The average Doctor Population Ratio is 8.03 in all Districts per one lakh population is not better in North Bengal. But at present, medical facility offered by Darjeeling is no match for its past glory. Since Darjeeling is the district headquarter Sadar or District Hospital is located here. However, the condition of these 308 bedded hospitals needs much improvement. Now hospital offers quality services to the resident of Darjeeling and their surroundings. As the regional headquarters of the Jalpaiguri district, the city of Jalpaiguri has a prominent position in North Bengal. The nearby population in the region often flocks to the city to get proper health care services. This position is amplified by the systemic industrial development of the district and rapid influx of people who needs proportionate medical care. Healthcare Facilities in Cooch Behar is quite effective with number of hospitals, path-labs, chemist shops and allied medical services. The citizens of the city enjoy well administered and well provided health services. Healthcare facilities in Cooch Behar are at par with other metro cities of West Bengal. But the problem of the health care facility in north Bengal is it mainly concentrated in the district town or particular in the blocks which are nearer to the main tow. The main problem is for the people who stayed in the blocks which is far from the district town so they could not access the medical facility due to their locational disadvantage for that parity should be there to improve the infrastructure for all the block hospital instant of concentrating a particular hospital or health centre. Although the government has taken initiation to improve the rural health care by

National Rural Health Mission which contribute a lot but it is not sufficient. Since the development of a region's health care facilities is intimately related to the wellness of that society, the government may seek for a strategy to raise the standard of those facilities from the ground up. Apart from economic condition, the social hierarchy or the system of social stratification existing in the society of West Bengal is likely to influence the health behaviour of individuals. Social stratification system determines the living conditions, privileges, obligations and cultural traditions surrounding the life of a person which in turn affect his perceptions regarding health, knowledge of health care and accessibility to health resources (SNM Kopparty, 1994). Who is responsible for this dilapidated health structure of North Bengal? This question echoes in the panorama of the broken health structure of the North Bengal.

CROP REGIONS IN TUNGABHADRA RIVER BASIN IN KURNOOL DISTRICT, ANDHARA PRADESH

B. Appanna and Dr. Y. Sujatha

Abstract

The current study focuses on the regionalization of crops in the Tungabhadra River basin of Kurnool District. The basin is characterized by a rural population, and agriculture serves as the primary source of livelihood for the inhabitants due to the lack of an industrial base. Traditional and subsistence agricultural practices have been prevalent in the basin for a long time. The basin consists of 45% block cotton soil and 30% red soil. Primarily farmers are cultivating this area like commercial crops, particularly cotton and groundnut, along with food grains such as bengal gram, red gram, fruits, and vegetables. The choice of crops grown in the basin during an agricultural year is greatly influenced by physiographic, climatic, soil, and socio-economic conditions, as well as the people's are following traditional agricultural practices. As a result, specific crop regions have emerged in the basin. The study also examines the spatial variation at the mandal level in terms of temporal change, using data from two periods: 2009–10 and 2019–20. This paper aims to calculate and delineate crop regions based on a ranking method.

Introduction

The Tungabhadra River basin is located in the western part of the Kurnool district; it is characterized by its unique agricultural landscape. More than 75% of the region comprises Pedi plains, with 45% of the soil being cotton-rich block soils and 35 % of being red soils due to its geological connection to granite and gneisses. The primary mode of agriculture in this region is rain-fed, and agriculture stands as the predominant land use. Over 70% of the population relies on agriculture for their livelihoods. However, the agricultural system here is primarily based on traditional practices and operates at a subsistence level due to the limited availability of irrigation facilities and the prevalence of marginal and small landholdings. A significant portion of the working population is engaged in agricultural labor. In this particular context, the examination of crop regionalization assumes a crucial role in evaluating the arrangement and

distribution of crops across the basin. The concept of crop regionalization holds integral and significant within the realm of agricultural geography. Krishnakumari has expressed the view that the identification and demarcation of crop regions are immensely beneficial in the context of regional agricultural planning, particularly in optimizing crop cultivation. Agricultural regionalization holds a long-standing position in the field of agricultural classification and plays a crucial role in the planning and advancement of agriculture in developing nations. It serves as a tool to group together various agricultural phenomena, both apparent and hidden, across the Earth's surface. This tool allows geographers to partition an area into multiple regions based on the diversity found within the agricultural system. Moreover, it provides valuable insights into the spatial distribution of crops at a regional level (Dayalan, 2018). Therefore, a systematic investigation of agricultural regions based on crop associations is imperative for geographers as an initial step towards comprehensively understanding the Agricultural geography of the region. Ultimately, this aids in the planning and development of crops at a regional level. The objective of the present study is to identify the major crop regions in the Tungabhadra River basin of Kurnool district. The ranking method was employed to delineate the crop regions into primary (first rank), secondary (second rank), and tertiary (third rank) categories. The first three crops, regardless of their percentage of occupation were selected for the purpose of crop regionalization analysis. Given that the basin falls within a semi-arid climatic zone, effective planning is a great significance, and the present study sheds light on this aspect.

Study Region

The study area of the Tungabhadra River basin is in the north-western region of the Kurnool district in the state of Andhra Pradesh, India. It lies between North Latitude 15°15'00" to 16°'00" and East Longitude 77°0'0" to 78°15'00". The area falls within the Survey of India (SOI) Toposheet Nos. 57E/1 to 57E/16 and 57I/1 to 57I/5. The total area of the basin is 6,934 square kilometers. The basin consists of 30 mandals, with 21 mandals fully covered and the remaining 9 mandals partially covered. The basin receives an average annual rainfall of 670 mm and experiences temperatures ranging from 26°C to 46°C in the summer and 12°C to 31°C in the winter. The northwestern portion, which includes Adoni, Peddakadubur, Alur, Aspari, Chippagiri, Halaharvi, Holagunda, Pathikonda, Devanakonda, Krishnagiri, Veldurthy, Kodumur, and Kallur mandals, has a desolate appearance with vegetation mostly limited to small pockets of reserve forests. This portion of the basin covers an area of 41,712 hectares, which accounts for 4.46% of the total geographical area.

The terrain in this region slopes from south to north and is drained by the river Hundri, which joins the river Tungabhadra at Kurnool. The soils in the northwestern parts traversed by the river Hundri are black cotton, while the southeastern parts are predominantly pure red soils. Geologically, the basin is underlain by the crystalline rock of the Peninsular Gneissic Complex (PGC), which includes the granite gneisses and granite in the western and southern parts of the basin.

Objectives

(1) To identify and demarcate the crop regions, such as First, Second, and Third ranking crop regions, of the Tungabhadra River Basin for the years 2009–10 and 2018–19.

(2) To study the changes in crop regions during a 10-year period.

Data and Methodology

The current study has collected secondary data from the Chief Planning Officer (C.P.O.), Handbook of Statistics, Kurnool district, focusing on the general cropping pattern for two specific time periods: 2009–10 and 2019–20. The data has been collected at the 'Mandal' level, ensuring a comprehensive analysis. The data has been analyzed using basic statistical techniques such as percentages and averages. The objective of the study is to investigate the spatial patterns of crops that are ranked from first to third in terms of the percentage of the total cropped area, with a specific focus on First, second, and third crop regions. The first-order crop regions, which are those with the highest ranking, have been identified by considering the crops that contribute the highest percentage to the total cropped area in each of the component area units, regardless of their overall percentage. Similarly, second-order and third-order crop regions have been delineated based on their ranking in terms of percentage. In order to accomplish the objectives of the study, the percentages of different crops cultivated in the basin have been calculated and organized in descending order to define the crop regions.

Results and Discussions

First ranking crop regions or first order crop regions (2009-10)

Out of the 30 mandals, 11 mandals have groundnut as first-order crops, 10 mandals have bengal gram as first-order crop, 5 mandals have cotton as first-order crop, 2 mandals have red gram as first-order crop, 1 mandal has paddy as first-order crop, and one mandal has fruits and vegetables as first-order crops.

Groundnut and Bengal gram Region

Groundnut is the leading crop cultivated in the basin, with its cultivation spread across 11 mandals. The favorable environmental conditions in the basin have proven to be advantageous for the growth of groundnut, particularly on light mixed red and block soils. The distribution of groundnut cultivation is predominantly concentrated in the southern and central regions of the basin. It is the basin's second-largest crop cultivated as the first-ranking crop, next only to groundnut. Within the basin, it holds the top position in 10 mandals, namely Kurnool, Kallur, Orvakal, Kodumur, Gudur, Nanikotukur, Miduthur, Alur, Aspari, and Maddikera. The distribution of these mandals is predominantly concentrated in the northeastern and southwestern parts of the basin.

Cotton, Red gram Region

Cotton is the third most significant first-ranking crop cultivated in 5 mandals, namely Adoni, Kowthalam, Nandavaram, Mantralayam, and Holagunda. These mandals are primarily concentrated in the northwestern region of the basin. Red gram crop farming was limited to only 2 mandals, namely Bethamcherla and J. Bunglow.

Paddy and Fruits and vegetable Region

These are too tiny in their extent, as they comprise of 1 mandal each, i.e., paddy in Pagidayala mandal and fruits and vegetable crops in C. Belagal mandal.

First ranking crop regions or first order crop regions (2019-20)

In the year 2019–20, a total of 5 crops were observed in the primary crop regions, each with varying degrees of prominence. Among these regions, the cotton crop region stood out as the largest primary crop region, with 16 mandals. Followed by the Bengal gram region with 5 mandals, the red gram region with 4 mandals, the maize region with 3 mandals, and finally, the groundnut region with 2 mandals.

Groundnut, Bengal Gram and Cotton Region

As a first-ranking crop region, the groundnut crop is registered in two mandals, respectively, Krishnagiri and Tuggali mandals. Bengal Gram region is the 2nd largest first ranking crop region in Tungabhadra River basin during 2019–20, occupying five mandals located in a few mandals in the north-east and western mandals of the basin. The cotton crop is the dominant primary crop region among all other crops, and it was the first-ranking crop in 16 mandals.

It emerged as the largest crop region in the study area during 2019–20. Their concentration is high in the western, northern, and central mandals of the basin.

Red Gram and Maize Region

4 mandals, namely Dhone, Bethamcherla, Veldurty, and Peapully, are noticed as the first-ranking crop regions, with the red gram crop in the study area. The maize region is a newly formed primary crop region during the period 2019–20, replacing Bengalgram, paddy, and red gram crops. The region has been found in three mandals, such as Nandikotukur, Pagidayala, and J.Bunglow, which are located in the north-eastern part of the basin.

Changes in First Ranking Crop Regions (2009-10 to 2019-20)

Significant changes have occurred in the primary crop regions of the basin over a period of ten years. In the year 2009–10, six primary crop regions were registered, namely groundnut, bengal gram, cotton, red gram, paddy, and fruits and vegetables. Even after ten years, groundnut, Bengal gram, cotton, and red gram remained as primary crop regions. However, the crop regions of paddy and fruits and vegetables disappeared in 2019–20. A new crop region, maize, was recorded during this period. Other changes include an increase in the number of mandals (administrative divisions) in the cotton crop region (+11 mandals) and red gram (+2 mandals). On the other hand, there was a decrease in the number of mandals in the groundnut (-9 mandals), Bengal gram (-5 mandals), paddy (-1 mandal), and fruit and vegetable (-1 mandal) crop regions. Additionally, a new region for maize emerged, consisting of 3 mandals that were previously part of the Bengal gram, paddy, and red gram crop regions. (**Fig.** 1 and **Table-**1).

Second Ranking Crop Regions or Second Order Crop Regions (2009-10)

The second ranking of crops comprises a greater number of crops compared to the first ranking of crops. In the year 2009–10, a total of 10 crops were classified as second-ranking crops. Among these, Castor held the highest position with 8 mandals of the basin. These are located in the north-western and southern parts of the basin. Next in importance among the second ranking of crops is groundnut. It is extended to only 6 mandals, namely Kodumur, C. Belagal,Bethamcherla,Adoni, Aspari, and Maddikera. Bengal gram is the third-important second-ranking crop cultivated in 5 mandals. They are J. Bunglow,Kowthalam, Nanavaram, Holagunda, and Pattikonda. The sunflower crop is the fourth important crop grown in 3 mandals located in the north-central part of the basin. They are in Kallur, Gudur, and Gonegandla.

Next in importance among the second ranking of crops are maize, fruits, and vegetables. The cultivation of maize is limited to 2 mandals, namely Nandikotukur and Pagidayala mandals. Similarly, the cultivation of fruits and vegetables is restricted to 2 mandals, namely Kurnool and Orvakal. Furthermore, there are several other crops, namely paddy, red gram, cotton, and tobacco, which are classified as the second ranking of crops in individual mandals. For instance, paddy is cultivated in Yemmiganur, red gram in Veldurthy, cotton in Alur, and tobacco in Miduthur mandals. (**Fig.** 2 and **Table-**2).

Second Ranking Crop Regions or Second Order Crop Regions (2019-20)

In the year 2019–20, there are five crops that contribute to the establishment of second-order crop regions. Groundnut, in particular, holds the most prominent position in the formation of these regions. As the second most significant crop, groundnut is cultivated in 9 mandals within the basin, specifically situated in the western and southern areas. Bengal Gram holds a significant position among the secondary category of crops, following closely after the primary ones. Its cultivation spans across 8 mandals. The distribution of Bengal gram is primarily concentrated in the northeastern region, with a few mandals also found in the southwestern part of the basin. The cultivation of cotton is the third most significant crop in terms of ranking, grown in 7 mandals. Additionally, paddy and fruit and vegetable crops are cultivated in 4 and 2 mandals, respectively.

Changes in Second Ranking Crop Regions (2009-10 to 2019-20)

In the years 2009–10, ten crops were reported as secondary crop regions, whereas in 2019–20, approximately five crops constituted secondary crop regions. An increase in the spatial distribution has been observed in cotton (+6 mandals), groundnut (+3 mandals), Bengal gram (+3 mandals), and paddy (+3 mandals). Conversely, a decrease in the number of mandals has been identified in castor (8 mandals), sunflower (3 mandals), maize (2 mandals), red gram (1 mandal), and tobacco (1 mandal). The fruit and vegetable crop region remained unchanged in terms of area, with 2 mandals in both 2009–10 and 2019–20.

Third Ranking Crop Regions or Third Order Crop Regions (2009-10)

Among the third-ranking crop regions of 2009–10, about 10 crops have been recorded in the basin (**Fig.** 3). Of these, Castor, Cotton, and Sunflower cultivation occupied first place in forming the largest third-order crop regions, as they comprised 5 mandals each, i.e., Castor in Gudur, Veldurthy, Pattikonda, Maddikera, and Gonegandla; Cotton in C. Belagal, Kosigi, Yemmiganur, Aspari, and Tuggali mandals; and Sunflower in Kurnool, Kodumur, Krishnagiri, Nandavaram,

and Alur mandal, followed by bengal gram (4 mandals); fruits and vegetables (3 mandals); red gram (2 mandals); maize (2 mandals); paddy (2 mandals); ground nut (1 mandal); and tobacco (1 mandal).

Third Ranking Crop Regions or Third Order Crop Regions (2019-20)

During the year 2019–20, eleven crops have been registered under tertiary crop regions with varied intensity. Fruits and Vegetables crop region emerged as the largest third ranking crop region with 9 mandals, followed by red gram (4 mandals), Bengal gram (3 mandals), paddy (3 mandals), groundnut (3 mandals), maize (2 mandals), condiments and Spices (2 mandals), cotton (1 mandal), jowar (1 mandal), minor millets (1 mandal), and chilies (1 mandal).

Changes in the Third Ranking Crop Regions (2009-10 to 2019-20)

Totally, about fourteen crops have been recorded in the study period under third ranking crop regions. They are castor, cotton, sunflower, Bengal gram, fruit and vegetables, red gram, maize, paddy, jowar, minor millets, chilies, condiments and spices, ground nuts, and tobacco. A decrease in the number of mandals under each third ranking region during the 10 years is observed in castor (-5 mandals), Cotton (-4 mandals), sunflower (-5 mandals), Bengal gram (-1 mandal), and Tobacco (-1 mandal). The increase in the number of mandals under each third ranking crop region during the 10 years of the study period is noticed in fruits and vegetables (+6 mandals), red gram, condiments and spices, and ground nuts (each with +2 mandals), paddy, jowar, minor millets, and chilies (+1 mandal). The maize region remained the same with two mandals, both in the 2009–10 and 2019–20 study periods.

Conclusion

During the years 2009–10, only six First Ranking crop regions, namely groundnut, Bengal gram, cotton, red gram, paddy, and fruits and vegetables, were noticed in the basin. Even after ten years, groundnut, Bengal gram, cotton, and red gram remained as First ranking crop regions. However, the crop regions of paddy and fruits and vegetables disappeared in 2019–20. A new crop region, maize, was recorded during this period. With regard to second ranking crop regions, ten crops were registered in 2009–10, and five crop regions, namely castor, sunflower, maize, red gram, and tobacco, disappeared in 2018–19, resulting in Five crop regions were recorded. About ten different third ranking crop regions have been reported in the year 2009–10 in the Tungabhadra River Basin, and eleven different third ranking crop regions have been noticed in the year 2019–20, with jower, minor millets, chilies, condiments and spices, and cotton as additional regions, replacing four crop regions of 2009–10, i.e., castor, Bengal gram, groundnut, and sunflower crop regions.

ANNUAL WATER BALANCE AND STREAM DISCHARGE MODELLING AT SHIMSHA WATERSHED OF UPPER CAUVERY BASIN, KARNATAKA

Dr. Surendra P. and Ms. Sneha Singh

Abstract

The present study mainly focuses on identifying the factors influencing water balance and stream discharge in Shimsha Watershed. The attempt also been made to analyse the water balance and stream discharge using SWAT model in the study area. Along with the use of SWAT model, geographical information system (GIS) is also used to estimate the HRUs, land use / land cover, calibrate and validate model and sensitivity analysis of SWAT model parameters for the Shimsha Watershed. The results show that Overall model performance was found to be agreeable as indicated by close relation between observed and simulated runoff. Model performance has been done using statistical parameter called Coefficient of Determination (R2). The R2 value were found to be 0. 64864 and 0.639706 after the calibration and validation. The model indicated very good agreement between simulated and observed flow. Therefore, it can be concluded that the SWAT model helps as an effective tool for assessment of water functioning at basin scale.

Introduction

Water is one of the most important natural resource. The Earth's water cycle is a dynamic and intricate system that plays a vital role in sustaining life and shaping our environment. Understanding the complex interactions of precipitation, evaporation, infiltration, runoff, and groundwater flow is crucial for effective water resource management, flood forecasting, and environmental protection. Hydrological models are useful tools that have been used in recent years to provide a visual representation of hydrological processes as well as accurate flow simulations, especially when evaluating the effects of land-use change and climate variability on hydrological cycles and water balance components. It encompasses a range of computational techniques that simulate the behaviour of water within a specific geographical area or watershed. By employing mathematical equations and algorithms, these models replicate the hydrological cycle, allowing us to observe and predict the movement

and distribution of water through the landscape. Hydrological models consider a multitude of factors, such as topography, land use, soil properties, vegetation cover, and climatic conditions, to create realistic representations of how water flows through a particular region. Water balance and stream discharge are important components of the hydrological cycle and are crucial for the management of water resources. Hydrological models provide a means to study the complex interactions between various hydrological processes in the Shimsha Watershed. While studying this we can analyse the relation between different parameters and how it is affecting the watershed Shimsha watershed covered with coconut plantation and medium dense urban settlement with using swat model what is the impact how the parameters are behaving within the watershed determined using the swat model. It is also important for the assessing water quality and pollutant transport within the watershed. Understanding the volume of water flowing through the stream helps in assessing pollutant loads and designing appropriate water quality management strategies in Shimsha watershed.

Study Region

The Shimsha River basin is a sub-basin of the Cauvery basin located in Karnataka, India. Geographically, it extends largely over two districts Mandya and Tumkur. The river has a course length of 221 km and has a catchment area of 8469 km^2 before joining the river Cauvery at shimshapura near the border of Chamarajanagara district. Shimsha river is an important tributary joining from left. The extent of area is latitude 13˚44′0″ N to 12˚8′0″N and Longitude 76˚8′0″ E to 77˚28′0″ E During the course of its travel from the origin many sub-tributaries join the Shimsha river such as Veeravaishnavi, Kanihalla, Chikkahole, Hebbahalla, Mullahalla and Kanva. At the mouth of the Shimsha river, a waterfall is situated at shimshapura in Malavalli taluk located 30 kms from Mandya, which was used to generate Hydroelectric power with an installed capacity of 17,200 kw and is considered to be the first ever hydroelectric project in Asia. The power generated during that time was used to light the Kolar gold fields. The Markonahalli dam, a multi-purpose reservoir has been erected across the river after it originates in Tiptur, Tumakuru district. It is reported to have been erected primarily as a flood-prevention measure for communities lying downstream, as well as to safeguard the safety of the nearby revered Yediyur Siddhalingeshwara Temple. Also, a barrage named after former Prime Minister H.D Devegowda has also been encountered during the course of its travel at Channapatna taluk, Ramanagara district – Igloor Dam Devegowda Barrage. The river then continues a southerly route and reaches

the Mandya district. The river travels in a south-eastern direction through Mandya district, with a waterfall at Shimshapura in Malavalli Taluk. Shimsha river is often referred as Madduru hole as the river passes through Maddur town and many villages of Maddur taluk. Shimsha is the principal irrigation supply for thousands of farmers in Nagamangala, Maddur, and Malavalli taluk, as well as hundreds of riparian villages in Tumakuru, Mandya, and Chamarajanagar taluks. The Shimsha Watershed is a geographical area in Karnataka, India, that is drained by the Shimsha River.

Objectives

(1) To analyses the water balance and stream discharge using SWAT model in study area.

(2) To identify the factors influencing water balance and stream discharge in study area.

Database and Methodology

In the present study following datasets were used to analysis the annual water balance and the stream discharge using SWAT model. Topography map was generated from the USGS-ASTER DEM with the spatial resolution of 30m. FAO – Digital soil map at the scale of 1:500000 used to create soil map. Land use and land cover map was derived from the ESRI Sentinel data with 10m spatial resolution. Followed by the rainfall data from IMD for the following years (1999-2022) and runoff (discharge) data from India water resources information system (WRIS) from 2001-2013 was used in this analysis. The following brief methodology was applied to assess the runoff and the water balance. The input data sets were derived from the above said data sources. Topography, soil texture, lulc, slope and rainfall layers were utilized as baseline parameters. From the DEM data watershed delineation and stream networks were generated. Followed by HRU analysis was carried with the support of DEM, Soil texture, lulc and slope along with rainfall in the SWAT model (SWAT RUN). Finally, surface runoff and the annual water balance were estimated for the Shimsha River basin.

Result and Discussion

SWAT Model Setup

The first step in model setup is to use a DEM raster file to delineate the watershed, sub- basins, and reaches. The definition of the watershed

gave a drainage pattern of land surface terrain, including the stream network and river basin outlets. The model used a DEM-based automated technique to delineate watershed. In which the watershed was divided into 7 sub watersheds, after providing a LU/LC map, soil map, and slope variation, they were further subdivided into 29 HRUs by the model (Hydrologic Response Units). HRUs, on the other hand, are combined units made up of homogeneous land-use and soil characteristics. A 10% threshold percentage has been implemented for all land use, soil, and slope classes in order to exclude minor land use, soil, and slope. The HRU report was then generated which included area of watershed (8694.15 km^2), detailed descriptions of the land use, soil, and slope classes in each sub- watershed.

Model Configuration

The SWAT model, is jointly developed by the United States Department of Agriculture – Agricultural Research Services (USDA–ARS), and Agricultural Experiment Station in Temple, Texas (Singh et al. 2013). By (Michael and Jain 2013), the computational components can be placed into eight major divisions namely: hydrology, weather, soil temperature, crop growth, sedimentation, pesticides, nutrients, and agricultural management, and uses physical inputs such as weather variables, topography, soil properties, land-management practices, and vegetation occurring in the catchment. SWAT explicitly models the physical processes related to water flow, sediment transport, crop growth, nutrient cycling etc. The form of water balance equation used to simulate the hydrologic cycle is depicted through equation.

(1) SWt = SWo + [Rday + Qsurf + Ea + Wseep + Qgw]

(2) SWt = Final soil water content in mm H2O,

(3) SWo = Initial soil water content in mm H2O, t time in days,

(4) Rday = Amount of precipitation on day i in mm H2O,

(5) Qsurf = Amount of surface runoff on day i in mm H2O,

(6) Ea = Amount of evapotranspiration on day i in mm H2O,

(7) Wseep = Amount of percolation and bypass exiting the soil profile bottom

(8) Qgw = Amount of return flow on day i in mm H2O

Watershed Delineation

Watershed is a hydrological unit from which runoff resulting from precipitation flows past a single point into a large stream, river, lake or pond. Watershed delineation

plays an important role in watershed management. Watershed delineation was performed in Arc GIS 10.4.1software. Digital Elevation Model (DEM) was use for watershed delineation. As top sheets provide information related to the location, drainage network and contours. Delineation of watershed has done using the dem, flow direction on map, flow accumulation on map, creation of outlet, snap pour point and watershed delineation.

SWAT Model Run

In this SWAT model to assess based on the Hydrological Response Units (HRUs) with the support of DEM (stream networks, watershed delineation, outlets for monitoring and sub basin parameter) and other thematic layers such as Land use land cover, soil, slope through overlay method. Include with this climatic dataset like rainfall and temperature which has been generated from the SWAT weather database (WGEN), followed by run the model to generate the runoff for the required number of years.

Hydrological Response Units (HRUs) Formation

The model simulates variations in evapotranspiration and other hydrological conditions for various land cover / crops and soils by subdividing the river basin into areas of exclusive land use and soil variations. The source of the hydrological modelling in SWAT is the HRU, which is a lumped land area within the sub-basin that is comprised of exclusive land cover, soil and slope. The sub-basin separation into HRUs improves precision and offers a much clearer physical description of the water balance. There are two options in SWAT for HRU allocation: either to assign a single HRU to each sub-basin or to assign multiple HRUs to each sub-basin (Srinivasan et al. 1998). If a single HRU per sub-basins is selected, the prevailing land use class and soil type surrounded by each river basin determines the HRU. If multiple HRUs are selected, the user must give a threshold level to ensure each grouping of land use and soil category within the sub-basin.

Sensitive Parameters

Sensitivity analysis can give a better understanding of the impact of change in an individual input parameter of the model response and can be performed using various methods. The method in the Arc SWAT interface combines the Latin Hypercube (LH) and One-factor-At-a-Time (OAT) sampling. Van Griensven et al. (2006), characterized Global rank 1 as “very important”, rank 2 to 6 as ‘important”,

rank 7 to 19 as "slightly important" and rank 28 as "not important". Sensitivity analysis was performed on 16 different SWAT model parameters for the Shimsha Watershed. Parameters and parameter ranges used in the sensitivity analysis. By using default upper and lower boundary parameter values, the parameters were tested for sensitivity using without observed streamflow data. The most sensitive factor governing the streamflow for the Shimsha Watershed was SCS runoff curve number for moisture condition II (CN2). This indicates that base flow is very significant in the water yield.

The Effective hydraulic conductivity in main channel alluvium (Ch_K2), threshold depth of water in the shallow aquifer required for return flow to occur (Gwqmn), available water capacity (Sol_Awc) and soil evaporation compensation factor (Esco) are also important parameters. Alpha_Bf and Sol_Awc were correlated to base flow and that could be the reason for their higher ranking in the sensitivity analysis. The sensitive parameters for the present study were selected based on the study conducted by Douglas – Mankin et al., (2010) on 64 selected watersheds. SWAT simulates the interaction of processes; many parameters affect more than one process. It's a kind of ripple effect. (For example, CN has direct impact on runoff; however, change in runoff changes other components of hydrology. There is direct impact of runoff change on soil erosion and nutrient transport affecting plant growth and nutrient cycling). So, Santhi et al., (2001) highlight this as the primary reason for manual calibration to start with hydrology balance and surface runoff, then sediment, and finally calibrating nutrients. From the above studies it was concluded to use the sensitive parameters such as CN2, ESCO, ALPHA_BF, SOL_AWC, SURLAG and RECH.DP and their initial and final values have been illustrated. The sensitive parameters are explained are as follows: Before calibration of CN2, ALPHA BF, GWQMN, ESCO, SOL AWC (84, 0.95, 0.8, 0.95, and 0.05) and after calibration of (35, 0.01, 0.05, 0.08, 1) respectively.

CN2

CN2 Initial SCS runoff curve number for moisture condition II. The SCS curve number is a function of the soil's permeability, land use and antecedent soil water conditions. The Soil Conservation Service Curve Number (SCS-CN) method is widely used in conceptual rainfall-runoff models for describing the runoff response with a curve, which is a function of the cumulative storm rainfall and antecedent wetness conditions. To improve the SCS- CN method.

ALPHA BF

ALPHA_BF Base flow alpha factor (1/days). The base flow recession constant, αgw, is a direct index of groundwater flow response to changes in recharge. Values vary from 0.1-0.3 for land with slow response to recharge to 0.9-1.0 for land with a rapid response. Base flow is the portion of streamflow that is delayed subsurface flow and generally maintained by groundwater discharge. Regardless of the specific climatic environment, its main features are tightly related to geological catchment properties. Base flow is the streamflow that constitutes the majority of the streamflow on a day when rain does not occur or has not occurred recently. Understanding the base flow process is important to deal with various water resources issues, such as water resources management strategies, low flow conditions assessment, hydrological modelling calibration, and water quality studies.

GWQMN

"GWQMN" stands for "Groundwater Quick Flow Manning's n" and it is a parameter used to represent the Manning's roughness coefficient for quick flow from the groundwater zone to the stream channel. In the SWAT model, accurate representation of groundwater dynamics and the interaction between groundwater and surface water is essential for realistic hydrological simulations. The GWQMN parameter contributes to this by influencing the rate of quick flow from the groundwater to the stream channel.

ESCO

ESCO stand for Soil evaporation compensation factor. This coefficient has been incorporated to allow the user to modify the depth distribution used to meet the soil evaporative demand to account for the effect of capillary action, crusting and cracks. ESCO must be between 0.01 and 1.0.

SOLAWC

It refers as the Soil Available Water Capacity parameter. This parameter is a key component of the model's representation of soil properties and their influence on water balance and hydrological processes within a watershed. Available Water Capacity (AWC) represents the amount of water that soil can hold and make available to plants for their growth and development. It is a crucial factor in determining how well a soil can retain and supply water to vegetation. The AWC parameter considers the soil's characteristics, such as texture, depth, and organic

matter content that influence its ability to retain water. Different soil types can have varying AWC values, and these values play a significant role in simulating various hydrological processes, including infiltration, runoff, evapotranspiration, and groundwater recharge. In SWAT, soil data are typically divided into different hydrologic response units, and each unit can contain multiple soil types. The "solawc" parameter is assigned to each soil type within an HRU, allowing the model to estimate how water moves through the soil layers, affects plant growth, and contributes to runoff and other hydrological responses.

Observed Discharge Data

The Runoff values for 18 years from 2004-2022 at the T.K Halli was simulated by the SWAT model and the comparison of output values with the observed data have been presented from which it can be seen that for most of the year, SWAT simulation seemed to overestimates the discharge when compared observed values. This is because of uncertainties in input data, model structure and model parameters. The calibration was carried out as a process of adjustment for these uncertainties. Due to continuous changes in the parameters the model simulated runoff and the observed discharge will correlate. The comparison between the observed and simulated discharge shows between 2004 to 2013. The Runoff values for 18 years from 2004-2022 at the T.K Halli was simulated by the SWAT model and the comparison of output values with the observed data have been presented from which it can be seen that for most of the year, SWAT simulation seemed to overestimates the discharge when compared observed values. This is because of uncertainties in input data, model structure and model parameters. The calibration was carried out as a process of adjustment for these uncertainties. Due to continuous changes in the parameters the model simulated runoff and the observed discharge will correlate. The comparison between the observed and simulated discharge shows between 2004 to 2013 (**Fig.** 1).

Surface Run-off Calibration

Most of the model inputs are physically based. The successful application of the model which are depends on how well the model is calibrated. The model will be calibrated using observed runoff data from the entire river basin. The calibration tool in the simulation menu of SWAT allows performing global changes on input parameters that are commonly modified during the calibration process. Calibration was performed manually from 2004 to 2005, and validation was performed from 2012 to 2013 run-off matches fairly well with observed runoff in trend and

magnitude. Overall, model performance was found to be agreeable as indicated by close relation between observed and simulated runoff. Due to changes in the sensitive parameters the model calibration done. The model efficiency checked using coefficient of determination or R square. This is a good method to signify the consistency among observed and good method to signify the consistency among observed and simulated data by following a best fit line. It ranges from zero to 1.0 with higher values indicating less error variance, and values greater than 0.50 are considered acceptable. In the calibration the R square was 0.64864 that's why this model is acceptable (**Fig.** 1).

Model Validation

Proper validation of the calibrated model is essential to understand its performance without any change in the input files except the climatic parameters. The monthly values of the maximum and minimum temperature for the time period for which the model is being validated is set as the input data for the model. The model was validated for similar parameters. Monthly run-off was compared for the river basin, as per the availability of observed data. In validation of the model the R square was 0.639706 which is acceptable. In the calibration and validation, the values of R square are more than 0.5 which is acceptable and is a good sign of model efficiency. So, the model is running properly and due to this model can run the future simulation also but in some points in graph the simulated and the peaks and are not matching is due to the uncertainty in the model's parameters and the input dataset. But the overall model is working properly and efficiently. The discharge is simulated in between 2020 to 2022. Due to the validation and calibration of model is running properly and can be used for future reference. This will help in future simulation as well managing the water movement in the study area will become very efficient. But there is still scope for future use ability of the model (**Fig.** 2).

Water Balance

This is the balance between the inputs and outputs of a drainage basin. Water balance is expressed as:

$$P = Q + E \text{ (+/- change in storage)}$$

Whereas:

P = precipitation Q = run-off

E = evapotranspiration

Fig. 2

Rivers will always have a regime which they follow, in that some months the discharge of the river will be higher than others. The water balance looks at how the amount of precipitation compares with the water leaving the system as runoff or as evapotranspiration. This balance will change throughout the year and will be affected by the overall climate of the area near to the river. For example, under 'usual' conditions the precipitation will be matched by run-off and evapotranspiration giving a 'normal' river level. If evapotranspiration becomes greater for a few months in summer while precipitation and run-off remain the same, the river will flow below normal level. Key terms to describe various water balance conditions are, namely, (1) Water Surplus: there is excess water available to the system. This occurs when precipitation exceeds evapotranspiration and the excess is not being used by plants (2) Deficiency: there is a reduction of water available within the system. This occurs when evapotranspiration exceeds precipitation (3) Recharge: after a period of deficiency precipitation will occur and replace the lost water in the soil. This needs to occur before a period of surplus can reoccur (4) Field Capacity: The maximum amount of water that soil can hold before it becomes saturated. A surplus can result in wet soils, high river levels and additional run-off whereas a deficit lead to dry soil, falling river levels and possibly a drier micro climate. The soil water content is around 4%, the surface runoff is 38%, percolation is 26% and the evapotranspiration is 32%.

The percolation of water is less in the Shimsha watershed; this study area is facing problem in the depletion of ground water. The main reason for this area is due to deep bore well digging which cause the problem in the area. It's necessary to understand the relation between the various water balance components. Using swat model, it is easy to understand how water is actually behaving in the study area and how the role of water is changing. In this study results shows that overall, model performance was found to be agreeable as indicated by close relation between observed and simulated runoff. The Calibration and validation were performed manually for the year 2004 to 2005 and 2012 to 2013 respectively on monthly basis. The Model performance has been done using statistical parameter called Coefficient of Determination (R2). Also shows that after calibration and validation R2 value were found to be 0.64864 and 0.639706 respectively. The model indicated very good agreement between simulated and observed flow. Therefore, it can be concluded that the SWAT model helps as an effective tool for assessment of water functioning at basin scale.

Conclusion

As the population growing impulsively, demanding urbanization, the expansion of industries and development in agricultural practices adds up to the increasing demanding for water and it is very much essential to manage the resource wisely. In the present study, to understand the status of water resources as well as hydrological process in the Shimsha river basin, SWAT model was applied. Since the river Shimsha waters vast areas of cultivation land our study at estimating the surface runoff at ungauged stations for effective watershed management practices. Calibration and validation were performed manually for the year 2004 to 2005 and 2012 to 2013 respectively on monthly basis. Model performance has been done using statistical parameter called Coefficient of Determination (R2). After calibration and validation R2 value were found to be 0. 64864 and 0.639706 respectively. The model indicated very good agreement between simulated and observed flow. Therefore, it can be concluded that the SWAT model helps as an effective tool for assessment of water functioning at basin scale. Under practical conditions it may be difficult to install discharge gauges everywhere along the stretch of stream, and may be in the future it is necessary to know the surface runoff at a required stretch where the discharge gauge station facility is not available or gives faulty measurements.

ETHICAL DIMENSIONS OF PROMOTING GIRL CHILD EDUCATION FOR SOCIAL EMPOWERMENT

Dr. Mohd Akhter Ali and M. Kamrajum

Abstract

This research paper explores the ethical considerations and societal implications of promoting girl child education as a means of social empowerment. It examines the intersecting factors of ethics, education, and society, focusing on the ethical challenges faced in ensuring equal access to education for girls and the transformative potential of education in fostering gender equality and social progress. The paper investigates the ethical dilemmas associated with gender disparities in education, the social barriers impeding girls' education, and the role of society in addressing these challenges. By analysing existing research and case studies, it aims to provide insights into the ethical dimensions of girl child education and its impact on the empowerment of girls and the broader society.

Introduction

Education is a fundamental human right that plays a pivotal role in individual empowerment and societal development. This is particularly true for girls, as girl child education has far-reaching implications for gender equality, poverty alleviation, and overall social progress. According to the United Nations (UN) Sustainable Development Goals (SDGs), ensuring inclusive and quality education for all, including girls, is a critical target to achieve by 2030 (UN, 2015). This brief overview will highlight the significance of girl child education, emphasizing the transformative power it holds for individuals and societies. Individual Empowerment. Access to education equips girls with knowledge, skills, and confidence, enabling them to make informed choices, fulfil their potential, and participate actively in society. Education empowers girls by broadening their horizons, expanding their opportunities, and breaking the cycle of poverty. Studies have shown that educated girls are more likely to marry later, have healthier families, and pursue higher education and career aspirations (UNESCO, 2018). Furthermore,

education empowers girls to exercise their rights, promotes critical thinking, and fosters leadership qualities, enabling them to contribute meaningfully to their communities and advocate for their own rights (Ghosh, 2016).

Societal Development

Investing in girl child education yields significant societal benefits and contributes to broader development goals. Educated girls become agents of change, driving social progress and economic growth. Research indicates that increasing girls' education results in reduced infant and maternal mortality rates, improved child nutrition, and healthier communities (Lloyd, 2016).. Moreover, educated women tend to have fewer children, which positively impacts population growth and allows for greater focus on quality education and healthcare for future generations (World Bank, 2018). Educated girls also have a higher likelihood of participating in decision-making processes, contributing diverse perspectives, and promoting gender equality in all spheres of society (UNESCO, 2020). Girl child education is of paramount importance for both individual empowerment and societal development. It not only empowers girls to break barriers and fulfil their potential but also yields far-reaching benefits for communities and nations as a whole. By investing in girl child education, we foster a more equitable and inclusive society, where girls can thrive and contribute meaningfully to the social, economic, and cultural fabric of their communities (Ali, M., & Kamraju, M. 2022. Gender disparities in education give rise to various ethical concerns that highlight the need for equal opportunities for girls.

These concerns revolve around principles of fairness, social justice, human rights, and the promotion of inclusive societies (UNESCO, 2017). Firstly, gender disparities in education violate the principles of equality and non-discrimination, as equal access to education is a fundamental human right (UNESCO, 2017). Denying girls, the same opportunities for learning and personal development that boys enjoy raises ethical concerns about fairness and equal treatment. Secondly, gender disparities in education perpetuate social injustices by reinforcing and perpetuating gender-based stereotypes and norms (Sen, 1999) . Such disparities limit girls' ability to realize their full potential, pursue their interests, and contribute meaningfully to society. Ensuring equal educational opportunities is a matter of social justice, aiming to rectify historical disadvantages and create a level playing field for girls. Moreover, education is a crucial tool for individual empowerment and agency. It equips individuals, including girls, with knowledge,

skills, and critical thinking abilities necessary for making informed choices and pursuing their aspirations (Nussbaum, 2000). Denying girls access to education denies them the opportunity to develop their potential, exercise their agency, and actively participate in shaping their lives and communities. In addition to ethical concerns related to individual empowerment, gender disparities in education hinder socioeconomic development at individual, community, and national levels. Education is strongly linked to economic growth, poverty reduction, and improved health outcomes (World Bank, 2018). By excluding girls from education, societies miss out on their potential contributions to economic productivity, innovation, and social progress. Addressing these ethical concerns requires concerted efforts from various stakeholders, including governments, policymakers, communities, and families. It involves implementing policies and interventions that promote gender equality, eliminate discriminatory practices, and ensure inclusive and quality education for all (UNESCO, 2017). By providing equal opportunities for girls to access education, societies can uphold ethical principles, promote social justice, and foster inclusive and equitable societies. Promoting girl child education. Promoting girl child education holds significant transformative potential and has far-reaching societal implications. By ensuring equal access to education for girls, societies can experience positive changes across various dimensions. Here is an overview of the societal implications and transformative potential of promoting girl child education:

(1) Gender Equality and Women's Empowerment: Girl child education is a critical step towards achieving gender equality. It enables girls to break free from traditional gender roles, challenge stereotypes, and pursue their aspirations. Educated girls are more likely to participate in decision-making processes, advocate for their rights, and contribute to policy discussions, leading to greater gender equality and women's empowerment within societies.

(2) Economic Development: Education plays a crucial role in driving economic growth and reducing poverty. Promoting girl child education leads to a more skilled and educated female workforce, enhancing productivity and innovation. Educated women can secure better employment opportunities, earn higher incomes, and contribute to the economic development of their families and communities. The World Bank estimates that investing in girls' education can lead to significant economic returns for societies.

(3) Health and Well-being: Educating girls has a positive impact on health outcomes for both individuals and communities. Educated girls are more likely to make informed decisions regarding their health, seek healthcare services, and adopt healthy behaviors. They are also better equipped to address maternal and child health issues, leading to improved healthcare practices and reduced mortality rates. Promoting girl child education contributes to better overall health and well-being outcomes for societies.

(4) Social and Political Participation: Education empowers girls to actively engage in society and participate in social and political processes. Educated girls develop critical thinking skills, become more aware of their rights, and are more likely to challenge social norms and discriminatory practices. Their participation in community development, civic activities, and political decision-making brings diverse perspectives and contributes to more inclusive and representative societies.

(5) Sustainable Development: Promoting girl child education aligns with the United Nations Sustainable Development Goals (SDGs), particularly SDG 4 (Quality Education) and SDG 5 (Gender Equality). Education is recognized as a catalyst for achieving multiple development goals. Educated girls become agents of change, promoting sustainable practices, addressing environmental challenges, and contributing to sustainable development in their communities.

By recognizing and investing in the transformative potential of girl child education, societies can break cycles of poverty, discrimination, and inequality. Empowered and educated girls become catalysts for positive change, creating more inclusive, equitable, and sustainable societies for present and future generations.

Ethical Considerations in Girl Child Education

Exploring the ethical dimensions of gender disparities in access to education sheds light on the underlying issues of discrimination, cultural biases, and social norms that hinder girls' educational opportunities. The following points delve into these ethical considerations:

(1) Discrimination: Gender disparities in education are rooted in discriminatory practices that systematically disadvantage girls. Denying girls equal access to education based solely on their gender violates principles of fairness, equality, and human rights. Such discrimination perpetuates social and economic inequalities and denies girls the opportunity to develop their potential.

(2) Cultural Biases: Cultural norms and beliefs can reinforce gender-based stereotypes, limiting girls' educational opportunities. Societies that assign traditional roles to girls often prioritize domestic responsibilities over education. Challenging cultural biases and norms requires careful navigation, considering the need to respect cultural diversity while ensuring equal educational opportunities for girls.

(3) Social Norms: Social norms shape attitudes and expectations surrounding girls' education. These norms can discourage families from investing in their daughters' education, perpetuating the cycle of gender disparities. Addressing the ethical dimensions of social norms entails challenging traditional perceptions of gender roles and promoting a shift towards valuing and prioritizing girls' education.

(4) Intersections of Discrimination: Gender disparities in education intersect with other forms of discrimination, such as those based on socioeconomic status, ethnicity, disability, or geographic location. These intersecting dimensions exacerbate the challenges faced by marginalized girls, compounding the ethical concerns surrounding their access to education. Efforts to address gender disparities in education should consider and address these intersecting forms of discrimination.

(5) Human Rights and Social Justice: Ensuring equal access to education for girls is not only a matter of human rights but also an ethical imperative rooted in principles of social justice. Every child has the right to education, regardless of their gender. Failing to address gender disparities in education perpetuates social inequalities and hinders societies from achieving inclusive and equitable development.

Recognizing and addressing these ethical dimensions requires a multifaceted approach. It involves promoting inclusive policies, challenging discriminatory practices, and fostering societal shifts towards gender equality and girls' empowerment. Ethical considerations in girl child education call for proactive measures to dismantle barriers, challenge biases, and ensure equal educational opportunities for all children, irrespective of their gender. Addressing gender disparities in education and ensuring equal educational opportunities for girls presents several ethical challenges. These challenges arise from complex social, cultural, and economic contexts and require thoughtful consideration and action. The following points discuss the ethical challenges associated with addressing these disparities:

(1) Cultural Sensitivity and Respect: Promoting girls' education while respecting cultural diversity can be a delicate balancing act. It requires acknowledging and appreciating diverse cultural norms and values while challenging discriminatory practices that hinder girls' education (Freeman, 2004) . Ethical challenges arise in navigating cultural sensitivity and ensuring that interventions do not inadvertently undermine cultural identities or perpetuate cultural imperialism.

(2) Overcoming Resistance and Changing Attitudes: Resistance to change and deeply ingrained attitudes and beliefs can pose significant ethical challenges. Challenging deeply rooted gender biases and stereotypes requires engaging with communities and addressing their concerns and misconceptions. Ethical considerations include promoting dialogue, fostering understanding, and building consensus to overcome resistance to girls' education (Sutton, 2011).

(3) Resource Allocation and Prioritization: Ethical dilemmas emerge when limited resources must be allocated among competing priorities. Governments and organizations face challenging decisions in distributing resources to address gender disparities in education. Balancing investments in girls' education with other pressing needs, such as infrastructure development or healthcare, requires ethical considerations in ensuring equitable resource allocation (Zaidi, 2012)..

(4) Sustainable and Context-Specific Interventions: Implementing sustainable interventions that address gender disparities in education necessitates understanding the specific contexts, needs, and aspirations of girls within different communities. Ethical challenges arise in developing interventions that are contextually relevant, sensitive to local dynamics, and responsive to the unique challenges faced by girls in various socio-cultural settings (Moosa, 2020) .

(5) Intersectionality and Inclusivity: Ethical considerations arise from the recognition that gender disparities intersect with other dimensions of identity, such as socioeconomic status, ethnicity, disability, or geographic location. Ensuring inclusivity and addressing the needs of marginalized girls requires an intersectional approach that acknowledges and responds to the unique challenges faced by different groups of girls (Crenshaw, 1989).

Addressing these ethical challenges requires a comprehensive approach that incorporates principles of justice, fairness, and respect for human rights. It involves engaging with communities, fostering dialogue, and tailoring interventions to specific contexts. Furthermore, addressing gender disparities in education should involve collaboration with diverse stakeholders, including governments, communities, civil society organizations, and international bodies, to collectively navigate the ethical challenges and work towards achieving equal educational opportunities for all children. Investing in girl child education carries significant ethical implications and has the potential for positive impacts on society. By understanding and addressing these ethical implications, societies can promote social justice, equality, and sustainable development. The following points examine the ethical implications of investing in girl child education and its potential positive impact on society:

(1) Ethical Imperative of Equal Opportunity: Investing in girl child education aligns with the ethical imperative of providing equal opportunities for all individuals. Education is a basic human right, and denying girls access to education is a violation of their rights to equality and non-discrimination (UNESCO, 2015) . By investing in girls' education, societies uphold principles of fairness, justice, and human rights.

(2) Empowerment and Agency: Education empowers girls, enabling them to exercise their agency, make informed decisions, and participate actively in society. Ethically, investing in girl child education acknowledges and supports the agency and autonomy of girls, enabling them to shape their lives and contribute to the betterment of society (Nussbaum, 2000) . Empowered girls become agents of change, promoting gender equality, social progress, and sustainable development.

(3) Breaking the Cycle of Poverty: Education is a powerful tool for breaking the cycle of intergenerational poverty. Investing in girl child education can lead to improved economic opportunities, higher incomes, and enhanced socioeconomic well-being for girls and their families (World Bank, 2018) . Ethically, by breaking the cycle of poverty, societies reduce inequalities and promote social inclusion.

(4) Health and Well-being: Education is closely linked to improved health outcomes for individuals and communities. Educated girls are more likely to make informed decisions regarding their health, adopt healthier behaviours, and contribute to healthier families and communities (UNESCO, 2017).

Ethically, investing in girl child education contributes to the promotion of health, well-being, and the fulfilment of individuals' right to health.

(5) Sustainable Development: Investing in girl child education is a strategic investment in sustainable development. Educated girls become agents of change, promoting sustainable practices, addressing environmental challenges, and contributing to the achievement of the United Nations Sustainable Development Goals (SDGs) (UNESCO, 2018) . Ethically, investing in girls' education acknowledges the interconnectedness of social, economic, and environmental well-being and the need for a holistic approach to development.

By recognizing the ethical implications and investing in girl child education, societies promote social justice, gender equality, and inclusive development. Empowering girls through education not only benefits individuals but also leads to positive societal transformations, fostering a more equitable, prosperous, and sustainable future.

Societal Barriers and their Ethical Implications

Societal barriers to girl child education pose significant ethical implications as they perpetuate inequality, restrict opportunities, and hinder social progress. These barriers arise from deep-rooted social norms, cultural practices, and systemic issues that must be addressed to ensure ethical and equitable access to education for all children. The following points examine some societal barriers and their ethical implications:

(1) Gender-Based Discrimination: Gender-based discrimination is a pervasive societal barrier that denies girls equal access to education. Discriminatory practices, such as early marriage, gender stereotypes, and biased cultural norms, limit girls' educational opportunities. Ethically, such discrimination violates principles of equality, fairness, and human rights, undermining girls' potential and perpetuating social inequalities.

(2) Child Marriage and Early Pregnancy: Child marriage and early pregnancy are significant barriers to girls' education. These practices not only deny girls the opportunity to complete their education but also expose them to health risks and limit their future prospects. Ethically, addressing child marriage and early pregnancy is crucial for protecting girls' rights, promoting their well-being, and ensuring their equal access to education.

(3) Socioeconomic Constraints: Socioeconomic barriers, including poverty, lack of financial resources, and economic inequalities, hinder girls' access to education. Ethically, it is imperative to address these constraints to ensure equal opportunities for all children, irrespective of their economic background. Tackling socioeconomic disparities requires targeted interventions, resource allocation, and equitable policies that prioritize education as a fundamental right.

(4) Cultural Norms and Stereotypes: Cultural norms and stereotypes often reinforce traditional gender roles and perpetuate biases against girls' education. Ethical considerations arise in challenging these norms while respecting cultural diversity. Balancing cultural sensitivity with the promotion of equal educational opportunities requires engaging with communities, fostering dialogue, and promoting awareness about the importance of girls' education.

(5) Lack of Infrastructure and Resources: Inadequate educational infrastructure, such as schools, classrooms, and sanitation facilities, can disproportionately affect girls' access to education. Limited availability of educational resources, including textbooks, teaching materials, and technology, further exacerbates disparities. Ethically, addressing these barriers requires investment in infrastructure development and resource allocation to ensure inclusive and quality education for all children.

(6) Gender-Based Violence and Safety Concerns: Gender-based violence and safety concerns in and around educational institutions create a hostile environment for girls, deterring them from attending school. Ethical implications arise in ensuring a safe and secure learning environment that protects the rights and well-being of girls. Combating gender-based violence and addressing safety concerns is essential to creating an ethical educational ecosystem (Pranathi, O., & Kamraju, M. 2023) .

Addressing these societal barriers requires collective action, involving governments, civil society organizations, communities, and individuals. Ethical considerations call for transformative measures that challenge discriminatory practices, promote gender equality, and uphold the principles of fairness, justice, and human rights. By removing these barriers, societies can create an inclusive and equitable education system that empowers girls, promotes social progress, and fosters a more just and sustainable future.

Role of Society in Promoting Girl Child Education

(1) Ethical Responsibilities of Stakeholders: Various stakeholders, including governments, policymakers, educational institutions, communities, and families, have ethical responsibilities in promoting girl child education. Governments and policymakers bear the responsibility of enacting and implementing policies that ensure equal access to education for all children, regardless of their gender (UNESCO, 2015) . Educational institutions should create inclusive environments free from discrimination, while communities and families must actively support and encourage girls' education, challenging harmful gender norms and stereotypes.

(2) Importance of Community Involvement: Community involvement plays a crucial role in promoting girl child education. Communities can create a supportive environment by recognizing and valuing the importance of girls' education. Engaging community leaders, parents, and local organizations in dialogue and decision-making processes helps address cultural barriers, dispel myths, and foster acceptance of girls' education (Gupta, 2013) . Ethically, community involvement ensures that interventions are contextually relevant, sustainable, and respectful of local customs.

(3) Awareness Campaigns and Advocacy: Raising awareness about the importance of girl child education is essential for creating a supportive environment. Awareness campaigns and advocacy efforts can challenge societal perceptions, highlight the benefits of educating girls, and mobilize public support (Ghosh, 2019) . Ethically, advocacy campaigns promote social justice and human rights by challenging discriminatory practices and influencing societal attitudes towards girls' education.

(4) Successful Initiatives and Interventions: Numerous successful initiatives and interventions have addressed ethical challenges and promoted girl child education. For example, the Kishoree Kontha program in Bangladesh focuses on empowering adolescent girls through education, life skills training, and community engagement (World Bank, 2020) . The Room to Read organization implements interventions that address cultural and economic barriers, providing girls with access to quality education in various countries (Room to Read, n.d.). These initiatives highlight the importance of context-specific approaches, community involvement, and multi-stakeholder partnerships in promoting girl child education ethically.

Integrating ethical considerations into interventions involves promoting social justice, equity, and human rights. It requires engaging with stakeholders, fostering dialogue, and ensuring the participation of marginalized communities. By recognizing and fulfilling their ethical responsibilities, stakeholders can collectively contribute to creating an enabling environment that supports and promotes girl child education.

Conclusion

In conclusion, the research highlights the ethical dimensions of promoting girl child education and the transformative potential it holds. It emphasizes the ethical responsibilities of various stakeholders, including governments, policymakers, educational institutions, communities, and families, in ensuring equal access to education for girls. The research underscores the importance of addressing societal barriers, such as discrimination, cultural biases, and social norms, which hinder girls' education and perpetuate inequality. Investing in girl child education is not only an ethical imperative but also a pathway to empowering girls and fostering social progress. Education equips girls with knowledge, skills, and agency, enabling them to overcome challenges, make informed decisions, and contribute positively to society. By providing equal educational opportunities, societies can promote social justice, gender equality, and sustainable development. However, there are ethical challenges associated with addressing gender disparities in education. These challenges include cultural sensitivity, overcoming resistance to change, resource allocation, developing context-specific interventions, and addressing intersectionality and inclusivity. Tackling these challenges requires collaborative efforts, dialogue, and transformative measures that uphold principles of fairness, justice, and human rights. Further research is needed to deepen our understanding of the ethical implications of promoting girl child education and to identify effective strategies to overcome barriers. Policy changes should prioritize girls' education, allocate resources equitably, and address systemic issues that perpetuate gender disparities. Collective action involving governments, communities, civil society organizations, and individuals is necessary to ensure equal access to education for all children, irrespective of their gender. In conclusion, promoting girl child education is not just an ethical imperative but also a means to create a more inclusive, equitable, and prosperous society. By recognizing and addressing the ethical challenges, we can unlock the full potential of girls, empower them as agents of change.

GEOPOLITICAL CONFLICT SITUATION AND PERSPECTIVE- A CASE STUDY OF INDIAN OCEAN

Dr. Navneet

Abstract

The geopolitics of the Indian Ocean region holds paramount significance in the contemporary global landscape. This paper delves into the multifaceted dimensions of Indian Ocean geopolitics, encompassing historical, economic, environmental, and strategic considerations. Employing a comprehensive methodology that incorporates geopolitical databases, economic and trade statistics, environmental data, and historical archives, the study aims to unravel the intricate interplay of actors, interests, and power dynamics in the region. The Indian Ocean, boasting critical choke points like the Strait of Hormuz and Bab-al-Mandeb, serves as a nexus for international trade and political activities. As the repository of a substantial share of the world's oil, gas, uranium, gold, and diamond reserves, the Indian Ocean region emerges as a focal point for global economic dynamics. Furthermore, it houses vital minerals, amplifying its strategic importance. The region's geopolitical landscape is marked by the presence of diverse littoral states, each with its unique historical trajectory, economic aspirations, and security concerns.

Introduction

Geopolitical analysis often examines the Earth's composition of land and water, a concept with a long history spanning hundreds of years. This perspective considers the interconnectedness of humanity, states, and the environment. The Earth can be categorized into hemispheres based on water and land distribution. The rise of globalization has amplified the importance of the Indian Ocean in economic affairs. In terms of size, the Indian Ocean ranks third globally, holding approximately 20% of the world's water. Analyzing the world map through Mercator's projection provides insight into the geopolitical importance of the Indian Ocean, which extends from 20 degrees E to 120 degrees E longitude. Notably, all nations along the Indian Ocean coastline, excluding Australia and South Africa, fall within the underdeveloped or developing categories. Furthermore, the majority of these nations comprise a significant portion of the Third World, sharing common

characteristics, notably having been part of colonial empires of Western European nations until gaining independence, primarily between the 1940s and 1960s. With limited exceptions, these nations were integral components of the colonial empires of Western European nations for substantial durations throughout the 19th and 20th centuries. They achieved liberation, whether through peaceful methods or other means, from colonial dominion between the 1940s and 1960s.

Study Region

This article is study of Indian Ocean region. The emerging nation-states facing heightened vulnerabilities and instabilities due to their underdeveloped status. Their ambitions and frustrations stem from the allure of development benefits on one hand and the constraints of economic backwardness on the other. These nations collectively grapple with the challenges and disruptions associated with the shift from traditional cultural values to those required by industrial economies in the nuclear age. Access to the ocean can be gained through either two narrow northern "choke-points" – the Suez Canal/Horn of Africa and Singapore/Straits of Malacca – or two southern border "gateways" at the southern extremities of Africa and Australia. The southern Indian Ocean, in reality, provides the most direct route between the Pacific and Atlantic Oceans. Moving beyond the coastal states, the northern landmass is primarily shaped by the influence of the Soviet Union and China, both Communist powers in ideological conflict with the Western world. Specifically, the Soviet Union, as a superpower, has been in a conflict with the United States, the other superpower. Strategically, the Indian Ocean region represents a vulnerable aspect for the Soviet Union, with limitations in reducing its vulnerabilities. Following the British announcement in 1968 regarding their withdrawal from the Indian Ocean Region by 1971, the two superpowers – the United States and the Soviet Union – became deeply involved. The subsequent two decades witnessed an escalation in militarization and superpower rivalry. The economic and political aspects of the Indian Ocean have seen growth alongside the expansion of globalization.

Objectives

(1) The significance of Indian ocean in geopolitics of region

(2) How is Indian Ocean strategically important for India?

(3) Why United States is interested in Indian Ocean region?

(4) Why china wants its domination in Indian Ocean?

Database and methodology

This article used primary and secondary data. Articles, books, newspaper, government documents, reports. Utilize geopolitical databases that compile information on international relations, conflicts, and geopolitical events. Access databases that provide economic and trade statistics for countries in the Indian Ocean region. International organizations like the World Bank and the International Monetary Fund (IMF) offer comprehensive datasets. Explore historical archives and libraries for primary sources that offer insights into historical geopolitical events in the Indian Ocean region. The methodology used in article is qualitative. Analysis of indian ocean rgionis conducted to know its significance. Conduct a thorough literature review to understand existing theories, frameworks, and scholarly work on Indian Ocean geopolitics. Identify gaps or areas for further exploration. Analyze specific case studies within the Indian Ocean region to gain a nuanced understanding of geopolitical dynamics. Focus on historical events, conflicts, or cooperative efforts. Explore different scenarios and potential future developments in the region based on geopolitical, economic, and environmental factors.

Results and Discussion

Initially, the United States demonstrated a lack of interest in filling the gap left by Britain's withdrawal from the Suez Canal. However, developments in the 1970s and 1980s compelled the U.S. to become involved in the Indian Ocean region. The U.S. strategically nurtured relations with China, capitalizing on the rivalry between China and the Soviet Union. Simultaneously, the U.S. refrained from intervening in South East Asia to allow China to reap the benefits. The U.S. directed its efforts toward maintaining influence in South Asia, West Asia, and Southwest Asia for its own strategic advantage. In contrast, the Soviets adopted a policy of supporting anti-imperialist forces and advocating for the independence of nations in former colonies. The shared anti-imperialist sentiment served as a basis for cooperation among states aspiring for socio-economic improvement in partnership with the Soviet Union. The Soviet Union aimed to diminish the influence of the United States in newly independent and developing countries, particularly given the growing collaboration between the U.S. and China. The Indian Ocean holds significance for trade and commerce, serving as a crucial link between the East and West. The political importance of the Indian Ocean has grown due to the ideological conflict between the two superpowers. According to the United States, the Indian Ocean is pivotal to its strategy of fostering positive relations and exerting influence in newly independent states. Conversely, the USSR views the U.S. strategy as a potential

threat to the sovereignty of these newly independent states and a hindrance to its own security. The geostrategic relevance of the Indian Ocean is heightened by its access to sensitive global areas and key choke points, such as the Malacca Strait.

Strategic Significance of Ports

China and India are making substantial investments in the development of seaports in the Indian Ocean, recognizing its strategic significance. India is actively involved in the construction of the Chabahar port in Iran, aiming to secure access to landlocked Central Asian countries. In response, China is building the Gwadar port in Pakistan, directly challenging India's interests. The presence of an anti-Sunni regime in Iran introduces vulnerabilities in the operational efficiency of the Chabahar port, posing challenges to India's maritime interests. In 2008, the Chief of the Indian Navy highlighted the strategic implications of the Gwadar port, emphasizing its potential to empower Pakistan in controlling strategically important energy sea lanes in the Persian Gulf. The growing geopolitical importance and cohesion of the Indian Ocean region are substantiated by at least three factors: the proliferation of regional strategic connections, the Indian Ocean policies pursued by external powers, and the collective indigenous responses to external intervention. The proliferation of regional strategic linkages underscores the increasing interconnectedness of events in the Indian Ocean area.

These events may be linked in two primary ways. Firstly, through a "linkage of instabilities," wherein the instabilities and imbalances in one sub-region not only affect neighboring countries but can also extend into more distant parts of the region, forming a comprehensive "linkage of instabilities" throughout the area. The impact of a situation may vary based on its occurrence, with implications differing for events near and further away. For instance, the Vietnamese invasion of Kampuchea has led to a significant refugee crisis and concerns about a direct security threat in Thailand, while in Indonesia and Australia, it is perceived as an unwelcome and perilous manifestation of regional instability. Similarly, the Soviet invasion of Afghanistan raised fears of a direct Soviet threat to Pakistan and Persian Gulf oilfields, causing apprehension in distant parts of the region about the means and objectives of Soviet policy. Consequently, due to such developments over the past decade, it is now improbable that any event impacting the security of even the smallest state in the Indian Ocean region will be dismissed as inconsequential to the other states in the area. Subsequently, interconnections arise among sub-regions when individual states or groups of states deliberately implement security policies on a scale beyond their immediate sub-regional context.

An example is the collaborative efforts of black states in southern Africa, in conjunction with other African nations, actively working to isolate and apply pressure on white-ruled South Africa. Similarly, there is widespread support from the nations along the Indian Ocean coast for the proposal to designate the area as a zone of peace. Another illustration is Saudi Arabia's policy, which seeks to integrate security postures from the Red Sea area through the Gulf to the extremities of the Indian subcontinent. Presently, the process of linkage seems fragmented, with states in one subregion generally not seeking security alliances with those in another. Security linkages have primarily been extra regional, involving a local state and an external power, such as Australia with the United States, India with the Soviet Union, and Pakistan with China and the United States. Although limited, the success of formal alliances between states of different subregions, as seen in SEATO (South-East Asia Treaty Organization) and CENTO (Central Treaty Organization), suggests the potential for more formal sub-regional coalitions in the future. Additionally, the Gulf Cooperation Council is progressing towards forming a security alliance, as previously mentioned.

The strategies of the two superpowers hold paramount significance. Their immediate concerns in the region have intertwined with the broader dynamics of their global competition, making the Indian Ocean a strategically vital arena for both. In contrast to Japan and Western Europe, which relied on Gulf oil for approximately 90% and 75% of their respective needs during the 1973-1974 embargo, the United States did not have a comparable dependence on Gulf oil. The significant outcome of the embargo wasn't just the impact on Western economies but the intense discord and internal conflicts within the Atlantic alliance. Member states and Japan engaged in fierce competition for privileged access to unembargoed oil and future access to Arab oil. The United States is eager to avoid a prolonged denial of Persian Gulf oil to the West, not only for economic reasons but also to maintain alliance solidarity. Despite the current surplus in global oil supplies and declining prices, Persian Gulf oil, constituting about 55% of the world's proven reserves, will remain strategically crucial for the West until the end of the century. In the past, the United States leaned on local allies to protect its fundamental political, economic, and strategic concerns in the Indian Ocean region. Yet, a shift occurred in the late 1970s, with the U.S. adopting a new strategy for its security interests in the area. This approach actively aimed to enhance access to naval, air, and communications facilities across the region. It involved improving the operational capabilities of the British-owned Diego Garcia, increasing naval deployments in the Indian Ocean,

and establishing the Rapid Deployment Force. These initiatives significantly strengthened the U.S.'s capacity to exert influence in the Indian Ocean, indicating a commitment to a more engaged role in the region. While the focus of these efforts might appear centered on the Persian Gulf, it is crucial not to characterize the policy as exclusively Gulf-centered. Although additional forces and facility improvements suggest a concentrated approach, U.S. military resources are limited and must be allocated based on strategic priorities. The emphasis on the north-west quadrant of the Indian Ocean highlights the importance Washington attributes to its Gulf interests and an overarching concern for the stability of that subregion. However, the U.S. has not neglected its military and political interests in other parts of the region, as evidenced by recent endeavors to strengthen military capabilities in the eastern approaches to the Indian Ocean, including securing landing rights for B-52 bombers in Australia

Non State Actors and their Threat

Non-traditional threats to global security have experienced significant growth, and India is grappling with major challenges such as maritime terrorism, gun-running, drug trafficking, and piracy along its sea borders. Given the crucial shipping lanes traversing the region, India has been underscoring the significance of maritime security in the Persian Gulf and the Gulf of Aden. Various terrorist organizations, including Al Qaeda, utilize maritime routes around India in the Indian Ocean region for narcotics and arms trafficking, financing their operations. Indian intelligence agencies have cautioned the government about potential seaborne attacks by terrorist groups targeting the nation's oil rigs, encompassing production and support platforms along both coasts. Piracy poses a significant threat in various parts of the Indian Ocean, notably the Malacca Straits and the Horn of Africa, necessitating a robust Indian maritime presence. Reflecting this perspective, the Indian maritime doctrine asserts that the arc from the Persian Gulf to the Straits of Malacca is a legitimate area of interest for India in the twenty-first century. The majority of attacks and hijackings on the high seas concentrate in three key areas: the Gulf of Aden and the eastern coast of Somalia, the coast of West Africa (particularly off Nigeria), and the Indonesian archipelago. In the initial quarter of 2008, over half of all attacks occurred in the Gulf of Aden. In 2008, a significant surge in piracy incidents took place, with at least 92 ships attacked in and around the Gulf of Aden, surpassing the number in 2007. An estimated $25 to $30 million was paid in ransom to Somali pirates. Responding to heightened concerns,

particularly after the hijacking of the merchant vessel MT Stolt Valor off the coast of Somalia in September 2008, the Indian government authorized the Indian navy to initiate patrols in the Gulf of Aden and provide escorts to Indian merchant vessels. India holds an economic stake in safeguarding not only Indian-owned but also non-Indian-owned cargo ships in the Gulf of Aden shipping lanes. Approximately 85 percent of India's sea trade on this route is transported by foreign-owned ships, and about one-third of India's entire fleet of 900 cargo ships operating in international waters is vulnerable to risks. The patrolling conducted by the Indian navy aims to secure the nation's sea-borne trade, instill confidence in the maritime community, and serve as a deterrent to pirate activities. While Russia, NATO, and EU forces have initiated patrols in the region, coordination efforts remain disjointed. India argues for the establishment of a peacekeeping force under a unified command to ensure security in pirate-infested regions for international shipping.

In a noteworthy operation—the first of its kind since the 1971 war with Pakistan—India's stealth frigate, INS Tabar, engaged and sank a pirate "mother vessel" in the Gulf of Aden, later revealed to be a Thai trawler. The Indian naval vessel fired in self-defense as the trawler, commanded by pirates who refused to surrender, posed a threat. This incident underscored the Indian navy's capabilities on the high seas, previously demonstrated during tsunami relief operations and the evacuation of Indian nationals in the Lebanon War of July-August 2006. The Indian navy showcased its autonomy and proficiency in serving a collective good: the protection of global maritime trade. India utilized this demonstration to project itself as a nation capable of safeguarding its maritime interests and commercial sea routes in international waters. While this highlighted the Indian navy's prowess on the high seas, questions were raised about its ability to counter terrorism on the home front, especially following a severe assault on Mumbai in November 2008, where terrorists managed to outwit the Indian navy and Coast Guard.

The terrorists successfully infiltrated Mumbai using a trawler, revealing a systemic failure within Indian security agencies. India's Coast Guard is responsible for securing the Exclusive Economic Zone within 200 nautical miles, while the navy oversees the blue water beyond. Despite the clear recognition of the threat of terror attacks from the sea, no measures were taken to reinforce anti-terror defenses. India's extensive coastline, coupled with insufficient policing, facilitates the clandestine landing of arms and explosives at isolated coastal points. This method was exploited in 1993 for the bomb blasts in Mumbai, and it was employed again in the 2008 terrorist attacks. The Indian Naval Chief took

responsibility for the lapse, citing weak infrastructure for patrolling and surveilling coastal areas. Despite actionable intelligence, both the Coast Guard and the navy failed to detect or intercept the Pakistani ship transporting terrorists from an Indus creek near Karachi, Pakistan. The escalating global threats from non-state actors necessitate India's collaboration with other major naval powers, not only to address issues like piracy but also to tackle broader security concerns for maritime commerce. Given the Indian navy's demonstrated effectiveness in providing the government with operational leverage in the Indian Ocean, its role in projecting power and safeguarding national interests is expected to grow. However, a significant challenge to the Indian navy may emerge from the expanding influence of another major Asian power in the Indian Ocean i.e. China.

In 2006, China surpassed Japan as the largest military spender in the Asia-Pacific, now holding the fourth-largest defense expenditure globally. While there is contention over the exact figures, with estimates ranging from China's official claim of $35 billion to the US Defense Intelligence Agency's estimate of $80-115 billion, the clear trend is a significant increase in Chinese military spending, showing a 195 percent rise from 1997 to 2006. The official Chinese figures do not encompass costs for new weapons purchases, research, or other major items for its secretive military. Calls for transparency in China's military intentions and capabilities have arisen globally, from Washington to Tokyo, Brussels, and Canberra. According to the 2006 Defense White Paper, China's navy aims to gradually expand its strategic depth for offshore defensive operations, enhance capabilities in integrated maritime operations, and develop nuclear counter-attacks. The Chinese navy now ranks as the third-largest globally, surpassing the Indian navy both qualitatively and quantitatively.

Historically a coastal force with a continental security outlook, China's economic rise since the 1980s has led to a maritime orientation with intentions to project power into the Indian Ocean. China is investing significantly more in modernizing its armed forces, particularly its navy, than India currently appears willing or able to sustain. China's growing submarine fleet, including sophisticated submarines, ballistic missiles, and GPS-blocking technology, positions it to potentially challenge the United States. There are indications that China plans to build an aircraft carrier by the end of the decade, a departure from its earlier focus on Taiwan. As China's economic and political influence expands, its profile in the Indian Ocean region has grown, with efforts to acquire naval bases along crucial chokepoints for economic and strategic purposes. China's comprehensive development of maritime power reflects

its ambition to dominate the strategic maritime space in the Indian Ocean region. To overcome the geographical distance, China relies on bases in the littoral regions of the Indian Ocean. The "String of Pearls" strategy exemplifies China's increasing naval power and encircling approach, particularly evident in its efforts to dominate the South China Sea and deploy submarines near the Strait of Malacca, a vital entry point to the Indian Ocean. Despite India's geographical advantage, China's expanding naval capabilities pose a strategic challenge for India in the region. China is actively pursuing the development of its maritime economy and aims to establish the world's largest merchant fleet, backed by extensive port and shipbuilding infrastructure. While China-India relations have been steadily improving since the 1990s, there has consistently been an underlying sense of competition. China has effectively cultivated strong ties with Pakistan through its economic and military influence. Although China aspires to dominate the Indian Ocean and achieve naval supremacy, this goal remains a distant prospect.

Indian Response to China in Indian Ocean

Strategic Partnerships: India has fostered strategic partnerships with countries in the Indian Ocean region to counterbalance China's influence. Bilateral and multilateral engagements with nations like the United States, Japan, Australia, and those in Southeast Asia have become more pronounced. Naval Modernization: India has been investing in the modernization of its naval capabilities to enhance maritime security. This includes the development of a robust naval fleet, acquisition of maritime surveillance systems, and the establishment of coastal surveillance networks. Infrastructure Development: India has been working on enhancing its maritime infrastructure, including port facilities, to strengthen its presence in the Indian Ocean. Projects such as the development of the Chabahar Port in Iran aim to provide India with strategic access to Central Asia. Diplomacy and Regional Cooperation: India has engaged in diplomatic efforts and regional cooperation to address common security concerns. Initiatives like the Indian Ocean Naval Symposium (IONS) and the Indian Ocean Rim Association (IORA) have been platforms for dialogue and collaboration. Focus on Maritime Domain Awareness (MDA): India has increased its focus on MDA to monitor and respond to maritime security threats effectively. This involves intelligence-sharing agreements, joint patrolling, and coordinated efforts with partner nations. Anti-Piracy Operations: India has actively participated in anti-piracy operations in the Gulf of Aden. The Indian Navy has deployed warships to ensure safe passage for merchant vessels and counteract piracy in the region. It's important to note that the geopolitical

landscape is dynamic, and developments may have occurred since my last update in January 2022. For the latest and more detailed information, please refer to recent academic publications, official government statements, or reputable news sources.

Conclusion

The Indian Ocean has evolved into a focal point for global economic and political endeavors, attaining strategic significance due to key chokepoints like the Strait of Hormuz and Bab-al-Mandeb. There exists a need for a renewed geopolitical framework for the Indian Ocean region, departing from traditional military-centric perspectives, and challenging the imperialist history of international maritime relations. The notion of 'mastery' or 'conquest' of the oceans must be reevaluated, recognizing the finite capacity of the marine environment and prompting exploration of new perspectives. Establishing a peaceful, socially equitable, gender-sensitive, and environmentally sustainable 'order' for the oceans requires patient negotiations and consensus-building, steering away from exclusively state-led management or region-specific development approaches. The Indian Ocean region and its coastal areas harbor over two-thirds of the world's oil reserves, 35% of global gas reserves, and significant proportions of uranium (60%), gold (40%), and diamond reserves (80%). Moreover, the region's importance is underscored by its mineral wealth, encompassing reserves of beryllium, coal, copper, iron, tin, chromite, manganese phosphate, and lithium. Positioned strategically, the Indian Ocean holds a unique geopolitical status, being the only ocean named after a country.

STUDY OF LITERACY GAP AMONG GENDER: A BLOCK LEVEL ANALYSIS OF LUCKNOW DISTRICT

Shashank Tripathi and Dr. Rana Pratap Yadav

Abstract

Literacy is the ability to identify, understand, interpret, create, communicate and compute, using printed and written materials associated with varying contexts. Literacy is considered an important key to social-economic progress. Literacy & education attainment are important indicators of the development of a society. It helps in eliminating gender disparity at all level. In India the reality of gender inequality is very complex and diversified because it exists in various fields like literacy, health, employment etc. According to the Census of India 2011, the overall literacy rate of India is 74% with male literacy being 82% & female literacy at 65%. A sizeable gender difference of 17% can be observed in the literacy rate. Such disparities between male and female literacy can be seen at both state and national levels. Recent decades manifest growth in literacy but the gap still exists and is predominant in rural areas. Lucknow district also witnesses gender disparity in literacy. The present study is an attempt to evaluate literacy gap among gender & its regional variations in the administrative blocks at the district level. This paper provides an insight into the Spatio-temporal patterns of male-female literacy & its level of disparity. This study is based on secondary sources of data collected from the District Census Handbook. The method adopted in the study to calculate the disparity in literacy is Sopher's Disparity Index (1974). Between the years 2001 and 2011, the study area has seen a fall in the gender gap and an increase in the male-female literacy rate. The gender literacy gap has been bridged largely due to initiatives like Beti Bachao, Beti Padhao, and the National Program of Education for Girls at the Elementary Level (NPGEL). But still, there is a scope for improvement in women's literacy levels for this the research will be useful in suggesting some relevant strategies and policies with implications for reducing gender inequality and promoting the dignified position of women.

Introduction

Literacy is a crucial indicator of the social and economic development of a nation. It plays a significant role in removing inequality along with the development of society and its individuals. It is the fundamental building block for a country's development. Literacy is a highly important tool for people to learn and develop skills that will enable them to understand and have a positive attitude for society. It also helps in analyzing the inequalities and factors responsible for poverty and exploitation in the society. Kofi Annan, Former Secretary General of the United Nations had quoted, "Literacy is a bridge from misery to hope. It is a tool for daily life in modern society. It is a bulwark against poverty and building blocks of development, an essential component to investments in roads, dams, clinics & factories. It is a platform for democratization & a vehicle for promotion of cultural & natural identity. It is the way to human progress & the means through which every man; woman & child can realize his or her full potential". The definition of literacy given by UNESCO (1957), "A person is literate who can with understanding both read and write a short simple statement on his/her everyday life". In simple words according to UNESCO it means "Literacy is the ability to identify, understand, interpret, create, compute & use printed & written material associated with varying contracts". According to Census of India 2011, "Any person (aged 7 & above) is considered a literate, if he or she can read & write in any language with complete understanding". Researchers, Academicians & policy makers have rated literacy as the starting point of development (Pattinson1982, Strect 1984).

Literacy unlocks the door to learning throughout life is essential, is essential to development & health & opens the way for democratic participation & active citizenship (Kofi Annan, Former Secretary General of the United Nations). Literacy influences & determines qualitatively & quantitatively not only human resources but also other demographic attributes like fertility, mortality, and economic participation of women &age of marriage ultimately aiming towards welfare of the society (Sawant & Lewis, 2004). Literacy is both the cause & result of development (Mohapatra,1993). Literacy is tool to empower women in the wider struggle against inequality & injustice in society (Patel & Dighe,1997). Higher levels of literacy are a good predictor of both a growing economy and a high standard of living. According to the Census of India 2011, the overall literacy rate of India is 74% with male literacy being 82% & female literacy at 65%. Uttar Pradesh recorded as a whole 77.3% of males & 57.2% of female literates. Lucknow district as a whole accounted for 82.6% of male & 71.5% of female literates respectively. At the national, state,

district, and block levels, disparities between males and girls in literacy can be observed. Recent decades have witnessed growth in literacy rate but the disparity in literacy still exists and can be predominantly seen in rural areas of the country. This is generally because the rural areas are dominated by agricultural activities while the urban regions are driven by the tertiary sector. Thus, a difference in economy, infrastructural facilities, accessibility, the standard of living, and women status can be observed. Differences in literacy are important for a variety of reasons. Due to the underutilization of potential human capital, a biased allocation of educational resources implies significant costs for social welfare. Some important factors like-poverty, early marriage, dowry, preference for boy's education, lower enrollment, etc are responsible for creating such disparities in literacy. Grover R.P., & Bhardwaj, R., (2002) have rightly pointed out that administrators & planners must pay greater attention in bridging the gap between literacy of males & females. As literacy is related to both social needs and economic development, there is a need to implement integrated literacy programs for rural development, with a particular focus on skill development and income generation programmes. A woman holds a pivot position & plays multiple roles in the development of modern society. It is widely argued, "When you educate a man, you educate a person; but when you educate a woman, you educate a generation." The Sustainable Development Goal (SDG) 4 also talks about ensuring inclusive & equitable quality education & promote lifelong learning opportunities for all. It will confront a holistic approach to educating people & boosting literacy levels to meet sustainable development goals that have yet to be made by 2030.

Study Region

Lucknow is the capital city of Uttar Pradesh which is located on the banks of river Gomti dividing the whole city diagonally into cis-gomti & trans-gomti regions . The total area of the district is 2528sq km. It exists between 26°30' to 27°10' North latitude and 80°34' to 81°12' East longitude. The district is surrounded in the northern side by district Sitapur, on the southern side by district Raebareli, on the eastern side by Barabanki district, on the south-western side by Unnao district & on the north-western side by Hardoi. The administrative setup of the district is divided into 4 tahsils & 8 development blocks namely Mal, Malihabad, Bakshi Ka Talab, Chinhat, Kakori, Sarojaninagar, Gosainganj & Mohanlalganj. There are total of 12 towns (10 statutory towns & 2 census towns. The adjoining districts are dependent on Lucknow district & mostly the Lucknow city for better education & health facilities & various job opportunities.

Objectives

(1) To find out the gender disparity in literacy rate.

(2) To suggest suitable measures for reducing disparities in literacy rate.

Database and Methodology

The present study is based on secondary data & sources obtained mainly from the Census of India, relevant issues, 2001 & 2011 & District Census Handbook of Lucknow-2001 & 2011. The block-wise data of the literate population & literacy rate for the 2001 and 2011 censuses are available. The tabulation and graphical representation of the data are done and represented through maps. The methodology adopted to measure gender disparity is Sopher's Disparity (1972). It is calculated using the following expression:

$$DI = \text{Log } X2/X1 + \text{Log } 100\text{-}X1/100\text{-}X2$$

Whereas: $X2 \geq X1$

DI- Disparity Index

X2- Percentage of Male Literates

X1- Percentage of Female Literates

Q- 100

To measure gender disparity in literacy, male literacy is taken as X2 & female literacy as X1, Where X2 is generally more than that X1. The Log value is taken to reduce the leveling-off effect (Sopher 1972). The value should range between +1 & -1. In the case of perfect equality, no disparity exists between the two variables. If the value is greater, it represents high disparity and if the value turns out to be lesser it shows low disparity. It is generally used in measuring the relative disparity. The study of the disparity index of literacy is grouped into 3 categories, namely, Low Disparity, Medium Disparity and High Disparity.

Results and Discussion

Being a universal phenomenon, the disparity in male-female literacy varies from region to region. The study area is also not free from this disparity. According to Census 2001, the total literacy rate of Lucknow district was 68.25% with male & female literacy rates being 75.98% & 60.47% respectively. With the passage of time, the study area witnessed a significant jump in total literacy by 77.3% with 82.6% as male literates & 71.5% as female literates in the 2011 Census (**Fig.** 1.)

Though, the disparity got narrowed down from the 2001 to 2011 census but, still, a large number of people are illiterates existing in the study region & acting as a major obstacle in the socio-economic development of the area. The present paper is an attempt to study regional variation of gender disparity in literacy in the study area by using Sopher's Disparity Index. This disparity is calculated for all the administrative blocks for the censuses 2001 & 2011. On the basis of values of literacy, the disparity index is calculated & by applying the standard deviation technique the study area is divided into low, medium & high disparity regions. The disparity was 0.45 in 2001 which came down to 0.36 in 2011 (**Table-**1 & **Table-**2 and Fig 2).

Table-1: Gender Disparity Index (GDI) in Literacy Rate, 2001

Blocks	% of literacy to the total population in Lucknow 2011				
	Total Literacy	Male Literacy Rate	Female Literacy Rate	Gap in Male-Female Literacy Rate (%)	Gender Disparity Index (GDI)
Mal	47.1	60.2	32.4	27.8	0.49
Malihabad	51.3	63.7	37.0	26.7	0.47
Bakshi Ka Talab	55.5	67.7	41.3	26.4	0.47
Chinhat	55.8	67.1	42.8	24.3	0.43

District (Rural)	53.9	65.9	40.1	25.8	0.45

Source: District Census Handbook of Lucknow, 2001

Areas of Low Disparity

In 2001, low disparity range (Below 0.45) was observed in 3 blocks namely Chinhat (0.43), Kakori (0.41) & Sarojaninagar (0.43). The highest rural literacy of 58.4% with 69.5% of male literacy & 45.5% of female literacy was recorded in Sarojaninagar block. In 2011 the same blocks except Sarojaninagar (0.38) i.e. Chinhat (0.33) & Kakori (0.32) were in the low disparity range (Below 0.36). This low disparity in these blocks can be attributed to good socio-economic development, high literacy, better opportunities for women, suitable environment etc.

Areas of Medium Disparity

In 2001, the medium disparity was between (0.45-0.48) range. Under this range, there were 3 blocks namely Malihabad (0.49), Bakshi Ka Talab (0.47) & Mohanlalganj (0.45). In 2011, medium disparity range (0.36-0.38), 2 more blocks were added in the range, now there were 5 blocks in total namely, Malihabad (0.37), Bakshi Ka Talab(0.37), Sarojaninagar (0.38), Gosainganj (0.36) & Mohanlalganj (0.37) (Fig 2 and **Table**-3 and 4).

Areas of High Disparity

In 2001, high disparity range (Above 0.48) was observed in 2 blocks namely Mal (0.49) & Gosainganj (0.49). The lowest literacy rate is witnessed in Mal block

with total literacy being 47.1%, the male & female literates being 60.2% & 32.4% respectively. In 2011, there was only 1 block i.e. Mal (0.40) which showed high disparity range (Above 0.38). Though, the overall iteracy was improved in the block with 64.3% with 74.3% & 53.3% as male and female literates but, the gender gap was widest with 21%.

Policy Measures

Being the largest populous state, Uttar Pradesh requires more efficient & inclusive policies to attain high literacy levels. The government needs to address the urgent needs in the education sector. To achieve socio-economic development following measures should be initiated: Education being a state subject, it is the responsibility of each state government to ensure the proper infrastructure of schools in rural areas, increase the number of teachers, incentives like textbooks, scholarships & free uniforms. The accessibility of educational facilities should be penetrated more in rural areas. All the administrative machinery at different levels should ensure proper functioning. Committees should be formed to ensure the proper utilization of funds allotted for improving literacy levels with a dedicated monitoring mechanism. (1) Social awareness campaigns should be launched to fight against the social evils existing in society like dowry the system, preference for a male child, child marriage, female infanticide, etc. The issues with education and literacy should be addressed by society as a whole. NGOs & civil society organizations play a vital role in enhancing awareness in society & educating individuals about the consequences of illiteracy (2) Due to various socio-economic constraints, the problem of early dropouts in rural areas can be observed. The National scheme Beti Bachao, Beti Padhao (BBBP) shows great success in encouraging the education of the girl child. Schemes like- UP Free Education Scheme, Kanya Sumangala Yojana (KSY), Bhagya Laxmi yojana, and Abhyudaya yojana, are important initiatives launched by the government to improve gender inequality.

'Mid-Day Meal' scheme is a scheme launched by the central government, under which mid-day meals are provided free of cost to the students of primary & junior primary schools. This programme has been a big success, but it should also focus on providing village children with sufficient nutrition & nourishment in addition to enrolling them in school. Recently, the Tamil Nadu government has supplemented midday meals in government schools with a breakfast scheme which is changing the dynamics of primary education & gross enrollment & active participation of the children in schools. (4) Job-oriented skill training, workshops, etc at secondary & higher secondary levels for girl children should be conducted to minimize gender discrimination. Vocational courses for- farming, dairy farming, handloom & textiles, poultry farming etc should be provided to the women of rural areas.

Conclusion

The paper is an attempt to evaluate the existing patterns of literacy rate & the level of the male-female disparity in literacy in the Lucknow district. The study area witnesses an increase in literacy rate from 53.9% in 2001 to 67.8% in 2011. However, a wide gap between male & female literacy can be observed. Though great numbers of female literacy can be seen from 40.1% in 2001 to 58.3% in 2011 in the study area, female literacy still lags behind male literacy. The female literacy rate of 58.3% is lower than the literacy rate of the male 76.4% population in 2011. The lowest literacy in 2001 was recorded in Mal & Kakori block with 47.1% & 50.4% respectively & in 2011, Mal & Gosainganj block recorded the lowest literacy with 64.3%. In 2001, the largest gap in gender literacy was seen in Mal & Gosainganj block with almost the same numbers of 27.8% & 27.7% while in 2011, the maximum gender disparity in literacy was seen in the Mal block with 21%. Chinhat block recorded a higher proportion of literacy rate in the urban area. Thus, it can be concluded that there exists an inverse relation between literacy & gender disparity. The literacy gap between men and women has narrowed through time, and this pattern should be continued in the future years.

CHALLENGES FACED BY WOMEN STREET VENDORS OF VARANASI CITY

Nitish Kumar Bhardwaj and Vishal Vikram Singh

Abstract

With the increasing rate of unemployment street vending has become a source of livelihood for a larger section of population. Uttar Pradesh records highest number of vendors followed by Madhya Pradesh. Vending is a source of livelihood with low capital and a temporary structure, which fulfills the goods and services need of the public. They mostly Belongs to the lower section of the society, and don't have the opportunity, education or skill to work in formal sector. So, they operating in the informal economy with no job security and uncertainty. The aim of this paper is to study the challenges faced by women street vendors in Varanasi city. For this purpose100 women street vendors were selected through simple random sampling method. The respondents were interviewed accordingly in order to access the information. Through the survey it was found that most of the female street vendors are between age group of 30-55 years. They are mostly married and sell fruits, flowers, vegetables, food items, clothes and other groceries. These women street vendors face many problems at their home and workplace. Lack of proper sanitation, unhygienic environment, unavailability of toilets are prominent issues as well as misbehaving of police personnel and local authorities at the workplace are common. The respondents told that working late night is also not safe. As a result of the efforts made by various NGOs and organizations for years, the Government of India has focused on the plight of street vendors and has created some policy and schemes for their progress like Street Vendor Act 2014, PM SVANidhi Scheme 2020. Nevertheless, most of the street vendors are deprived of these schemes due to ignorance and accessibility.

Introduction

Despite the existence of various constitutional and legal provisions safeguarding women's employment a large number of women workers, particularly in the unorganized sector suffer from various disadvantages relating to their

working lives as well as home. In 2005 the Confederation of Indian Industries (CII) commissioned a study titled 'Understanding the Levels of Women's Empowerment in the Work Place' revealed that women constitute only 6% of total workforce in corporate houses. The percentage of women in leading managerial positions is abysmally low. Only 7% labour force is in the organized sector and 93% work in unorganized or informal sector. Most of them are in street vending and others are engaged in household activities. The reason for the employment of women in such large numbers in the informal sector is women's weaker bargaining power, low skilled labour, generally lower wages than men and lack of unionization. Street vendors are those one who buy the goods at whole sale and sell it at retail price in the streets, road side, at bus stand or at other places of decent crowd for their daily livelihood. NASVI has defined street vendors as "a person who offers goods or services for sale to the public without having a permanently build structure but with a temporary static structure or mobile stall". Street Vending is one of the most visible aspects of the informal sector and practiced globally.

The major characteristics of street vending are low level of income, ease of entry, self-employed and it involves large number of people. About 80% of the population is engaged in the street vending. It does not only provide self-employment but also a means to provide affordable and convenient service (Jaishankar and Sujata, 2016). Street vending serves as important income generating activity which gives employment to sufficient number of poor women living in urban peripheral areas or slums. Street vendors sell their goods mostly on pavement and streets. However, street vending can be considered as an integral part of rural and urban economy characteristized with specific insecurities and challenges. The contribution of street vendors in generating a considerable amount of money in to the informal sector is often a crucial factor in driving the economy. Street vendors fulfill the requirements of the society and cater to the need of a sufficient number of customers especially from middle- and lower-income class. Women can be seen doing street vending along the pavements and streets. Mostly women enter in the street vending due their poor economic conditions. Their motive is to maintain their financial condition so as to fulfill their daily needs of the family. Apart from the problem of earning money for survival, women street vendors face several issues of uncertain and insecure working conditions at the workplace. Some major issues and problems faced by street vendors are lack of support, regular threat of eviction, and harassment by local officials and authorities. According to the report of ILO, 85 % of the street vendors face several health hazards.

It includes disease like increased depression, acidity, high blood pressure and increased blood sugar and others health complications. Except this, women face problem, related to sanitation, economic pressure, social cultural challenges, adverse political conditions and operational challenges (Tambunam. 2009). During COVID- 19 period Most of the women street vendors lost the means to work and livelihood which witnessed a significant fall in their income and earnings. With the loss in employment opportunities during COVID period, many of the women street vendors were not able to shift to alternative employment opportunities and were forced to continue with the same street-vending activity.

Study Region

Varanasi lying between 82°56' E to 83°03' E and 25°14'N. (also known as kashi or Banaras) is one of the oldest living cities in the world dating back 3000 to 5000 years. Being located on the crescent shaped bank of the Ganga River it is considered as cultural and spiritual capital of India. Due to high population growth and rapid development of the city during the decades of 1991 and 2000 it became a million city. Rapid urbanization has led to many urban problems such as pollution, living space, sanitation and unemployment. The increasing population and faulty government policies has forced a large segment of people towards the informal sector. In this Street vending has become a major source of livelihood for the people living in peripheral urban spaces. These people face several issues and challenges at their workplace. The present study is an attempt to highlight those issues and provide a better understanding of the factors operating therein.

Objectives

(1) The present study seeks to provide a better understanding of the demographic characteristics of women street vendors in the study area.

(2) To know the socio-economic and political constraints of women street vendors in Varanasi city.

(3) To evaluate the relevant issues and challenges faced by women street vendors at their Workplace and to provide insights of policy implications and remedial measures to deal with the issues and challenges faced by women street vendors.

Database and Methodology

The study is entirely based on primary data which have been collected through personal level survey in the study area. A structured interview schedule

containing pertinent questions related to the issues and problems faced by women street vendors in the Varanasi city was used in order to access the required data. Some open-ended questions were also incorporated in order to know the views and opinions of the women street vendors towards government policies, officials and local authorities. For the purpose of study, the samples have been choosen from five administrative zones of the Varanasi city namely, Varuna par, Kotwali, Bhelupur, Aadampur and Dashaswamedh. On the basis of simple random sampling method 20 sample have been taken from each zone and interviewed accordingly. Total 100 respondents have been interviewed and data have been analysed in order to draw conclusions. Data have been analysed and interpreted with the help of different tools like MS Excel 2012 and SPSS-22 version. Maps, charts and diagrams are incorporated wherever necessary. Maps have been prepared with the help of ARC GIS 10.3 software.

Results and Discussion

Results have been derived from the responses collected through the interview schedule which contained questions related to the respondent's demographic characteristics and the challenges being faced by them at their work place. An attempt has been also made to suggest the remedial measures and expected solutions.

Age; During the survey it was found that majority of the women street vendors were above 41-60 age-group. In most of the cases she herself was the head of the house and therefore they had taken the responsibility of earning the bread for themselves and their families. They also take care of other amenities in the house. It was also observed that 22 percent of women street vendors were between age group of 51-60. The younger age groups witnessed comparatively low proportion of women street vendors. Feeling unsafe is major factor behind such low proportion of women street vendors in the younger age groups. Being asked, the vendors told that their husband either do farming in the village or earn in the outer region through daily wages or help them in vending along road side, streets and pavements.

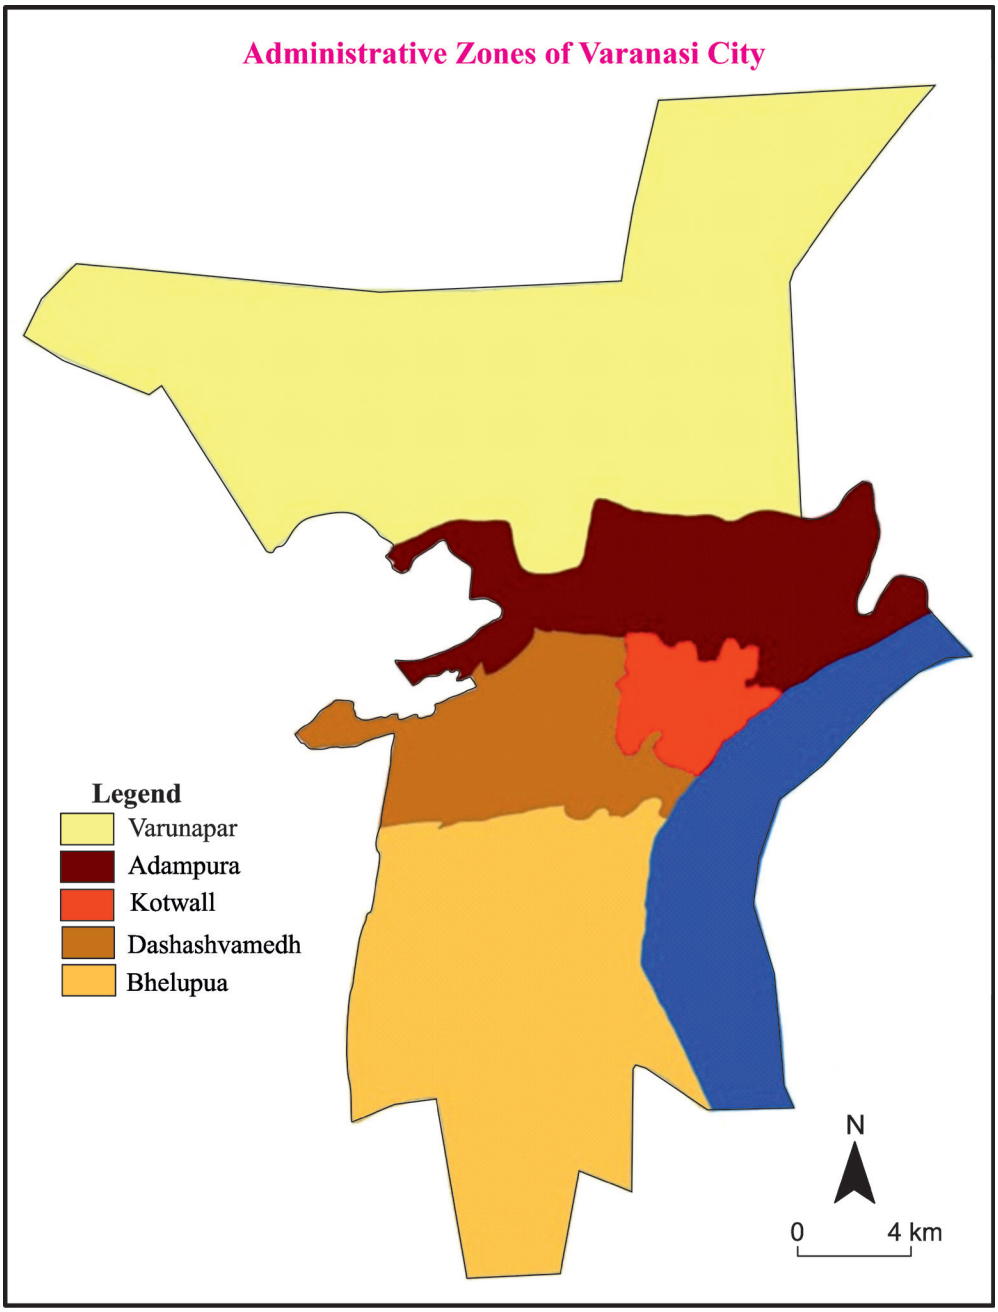
Marital Status: Marital status is another significant demographic characteristic which was considered during the survey. The data recorded reveales different nuptial categories of women street vendors in the Varanasi city. The highest percentage (78 percent) of women street vendors are married followed by 8 percent of unmarried women. This is because of the fact that married women street vendors of higher age groups feel more confident regarding feeling safe at the workplace in comparison to married and und unmarried women of the younger age groups.

Another significant demographic feature of the table is the proportion of widowed women street vendors in the city. It was recorded that 13 percent of women street vendors were widowed. This is the bitter fact of the Indian society that whenever a woman is widowed, she becomes economically vulnerable which forces her to do vending and other low level economic activities to run the livelihood of her family. Type of Street Vending: The responses during the survey portraits the proportions of women street vendors engaged in different stuffs in different zones of Varanasi city. It was observed that highest percentage (37 percent) of women street vendors were engaged in selling vegetables and fruits along the pavements and streets followed by 25 percent in tea and food stuffs while 25 percent of them were engaged in selling flowers and garlands. The highest proportion of women street vendors in selling vegetables and fruits along with other food items is due to easily availability of these items in the market. Another significant factors behind this may be the good returns and affordability of these items.

Access to Workplace Amenities

During the field survey the data was also collected regarding access to work place amenities like toilet facilities, availability of fresh drinking water, storage and alike in order to measure hygiene and sanitation at work place. The results found are quite disgusting that above 90 percent of women street vendors don't have facility of toilets, safe drinking water, storage and other amenities. Due to working in such a unhygienic environment the women street vendors are prone to several diseases like stress, hypertension and acidity (**Fig.** 1).

Awareness about Right and Interests: Responses were also recorded regarding the awareness of women street vendors towards their rights and interests. The data reveals that Majority of the respondents (88 per cent) disagree that the government protects the rights and interests of women street vendors. Another significant factor behind such situation is the ignorance and high level illiteracy among the women street vendors. Due to this most of the women street vendors are unaware of their rights and are often harassed by government officials and local authorities. Because they are illiterate or less educated and have no information about the government's plans and policies made for street vendors; local police exploit them at the workplace. These factors play crucial role behind the vulnerable conditions of women street vendors in Varanasi city. Proper measures and steps should be taken in order to safeguard the rights and interests of women street vendors in the study area. Harassed and Abused by the Authorities: In order to analyses the factors behind the vulnerable condition of women street vendors in Varanasi city



Administrative Zones of Varanasi City
Legend
Varunapar
Adampura
Kotwall
Dashashvamedh
Bhelupua
N
0
4 km

Fig. 1

the responses were also recorded know the status of being harassed, teased or abused by concerned government officials and local authorities. The study reveals that 70 per cent of the women street vendors in the city reported that they are being harassed and abused by the concerned city authorities or police at the workplace while 30 per cent of the respondents said that they are not being harassed by the city authorities or police. Being ignorant of their rights and safeguards provided by government policies these women street vendors are prone to exploitation through several means by police and local authorities. (**Fig.** 1)

Security at Work Place: Among the several significant constraints of women street vendors the prominent one is security at the workplace. There are sufficient number of studies which advocates for the safety of women street vendors while working late hours in the night. Due to several efforts government has drafted policies to safeguard the interests and rights of the women street vendors. In spite of this insecurity is the major issue for the women street vendors while working late hours in the Varanasi city. On the basis of responses recorded during the survey it was observed that 92 per cent of the women street vendors in the Varanasi city do not feel safe and secure while working late hours in the night. While only 8 per cent said that they feel secure even while working late hours in the market. As mentioned above security is the key issue among the several socio-economic barriers being faced by women street vendors in the Varanasi city.

Health Issues

Many studies reveal that street vendors work in severe unhygienic environment because of this they are prone to several diseases. In the Varanasi city an effort was made to record the responses of the women street vendors in order to know the status of hygiene and health issues. However the study conducted reveals that 41per cent of the women street vendors stated that they have health related disorders like blood pressure, Sugar, deafness, low vision while 59 per cent of the respondents said that they don't have any kind of health issues. As the study found that women street vendors don't have proper sanitation measures like toilets, fresh drinking water and air they are prone to several diseases.

Remedies

Some responses were also recorded in order to know the status of remedial measures. The data reveals quite disgusting factor that the women street vendors in Varanasi city don't believe that their status can be improved through policies and safeguards provided by government or some NGO organization. Most of the

women street vendors are of the view that their status can be improved only by themselves. According to the responses recorded 12 percent of the women street vendors said that their condition can be improved with the help of government initiatives, 15 percent said, it can be improved with the help of NGOs & their association and lastly, 73 percent said that it can be improved only through him/her self. The recorded responses show that there are many drawbacks and Loopholes which need to be taken care of while drafting and implementing the policies for women street vendors. It is also a bitter fact that association and NGO organization are not working well.

Conclusion

As mentioned, total 100 women street vendors were interviewed and their responses were recorded. 1. One significant demographic feature is that majority of women street vendors are between age group of 41-60. It may be because of the fact that women in comparatively older age groups feel more confident and safer at the workplace than those who are unmarried or in younger age groups. 2. Because of easy availability of in the local market majority of the women street vendors in Varanasi City were engaged in selling vegetables and fruits. Very few Of them are engaged in other economic activities. 3. Major socio-economic and administrative constraints being faced by the women street vendors are those of their basic necessities and amenities at the workplace like lack of hygienic space, toilets, feeling unsafe at the workplace during late hours and continuous harassment by local authorities, government officials and police. 4. The responses recorded during the survey reveals the fact that the policies and safeguards provided by government have some loopholes and drawbacks due to this most of the women street vendors are unaware of these policies. Other factors behind this may be the ignorance and illiteracy among the women street vendors or lame efforts of government officials in implementation and execution of these policies. However, it has been also reported that few of the women street vendors are receiving some kind of benefits from the government and they are keenly looking forward for their support and guidance. 5. There is a urgent need to take care of the issues and challenges being faced by the women street vendors in Varanasi city. The policies and safeguards should be implemented in a very effective manner so that it can cover most of the women street vendors. Other remedial measure which is to be taken is the proper education of the women street vendors so that it can enable them towards their rights and interests. Other amenities which are necessary at the workplace should also be taken care of like permanent place for vending, proper sanitation and hygiene etc.

BALANCING AGRICULTURAL DEMAND AND WATER RESOURCES: A STUDY OF IRRIGATION INTENSITY TRENDS IN MANDYA DISTRICT, KARNATAKA

Dr. Vishwanath, B.C. and Harish, H.S.

Abstract

Irrigation intensity in agricultural regions is influenced by various factors, including water source, quantity and quality, and channel network density. This study explores irrigation intensity variations in Mandya District, Karnataka, over the period 1991-2017, considering factors like cropping patterns, land-use efficiency, and adoption of cultivation methods. Mandya District, located in South India, is dissected into seven taluks. The study examines changes in irrigation intensity across these taluks, highlighting the district's geographical and agricultural diversity. The primary objective is to assess irrigation intensity changes in Mandya District from 1991 to 2017. Using historical documents and government reports, the study traces the evolution of water management in Mandya. Statistical analyses of net irrigated areas for 1991, 2001, and 2017 reveal shifts in irrigation methods. The intensity of irrigation is calculated using the ratio of net irrigated area to net sown area. Taluk-wise analyses and categorizations are conducted to understand spatial patterns. The findings indicate a significant increase in irrigation intensity from 41.4% in 1991 to 75.7% in 2017. Taluk-wise analyses reveal dynamic changes, with Mandya taluk consistently showing high intensity. Positive changes are attributed to canal construction, increased cultivable areas, well irrigation, and advancements in agriculture. Despite advancements, certain areas in Mandya remain rainfall-dependent, impacting crop productivity and income inequality. The study suggests utilizing rainwater through farm ponds and watershed structures. Emphasizing efficient canal water usage, including lining distributaries and field channels, is recommended. The district irrigation plan aims to mitigate drought, expand irrigated areas, and optimize water usage through innovative cropping patterns. This research provides valuable insights into the evolving landscape of irrigation intensity in Mandya District, offering a foundation for sustainable water resource management strategies.

Introduction

The term "irrigation intensity" usually refers to the amount of water used to irrigate a specific area of land. It measures how effectively water is used during the irrigation process. Irrigation intensity is commonly expressed in millimeters or inches and is calculated by dividing the total volume of water applied by the irrigated area. Irrigation intensity varies across agricultural regions due to a variety of factors such as irrigation source, water supply quantity and quality, and water channel network density. Cropping seasons, crop types, and other factors all have an impact on it. Cropping patterns, land-use efficiency, area yield efficiency, and the adoption of improved cultivation methods all benefit from increased irrigation intensity. The intensity of irrigation has a significant impact on agricultural productivity, water conservation, and environmental sustainability. Water stress and reduced crop yields can result if the amount of water applied is insufficient for the needs of the crops. Inadequate irrigation can also cause soil degradation and harm the agricultural ecosystem's overall health. Excessive irrigation, on the other hand, can result in waterlogging, soil salinity, and water resource waste. High irrigation intensity can also contribute to environmental issues like runoff, fertilizer and pesticide leaching, and negative impacts on local water bodies. Irrigation intensity is typically low in areas with limited infrastructure for expanding irrigation or where irrigation is used as a precautionary measure to address moisture scarcity in areas prone to heavy rainfall. All else being equal, irrigation intensity increases with decreasing rainfall and decreases with increasing rainfall in agricultural contexts. Irrigation intensity is typically low and negligible in rain-fed areas with constrained surface water, saline subsoil, and hilly or undulating topography. Typically, irrigation intensity is expressed in two ways, namely, the ratio of gross irrigated land to net irrigated land. The proportion of net irrigated land to net sown land.

Study Region

Mandya District is located in the South Indian Peninsula on the Mysore plateau, between 76° 19' and 77° 20' East Longitude and 12° 13' and 13° 04' North Latitude. It is bounded to the north by Hassan and Tumkur districts, to the east by Tumkur and Bangalore districts, to the south by Mysore district, and to the west by Hassan and Mysore districts. Mandya is the 19th largest district in Karnataka, covering a total area of 191,976 square kilometres (**Table-**1). Nagamangala, K.R. Pet, Mandya, Malavalli, Maddur, Pandavapura, and Srirangapatanna are the district's seven taluks. Notably, Nagamangala has the largest geographical area at 1,044.7 square kilometres, accounting for approximately 21% of Mandya's total area.

Table-1: Talukwise Irrigation Intensity in Mandya District 1991-2017

Source: Data compiled from Directorate of Economics and Statistics, Government of Karnataka, Bangalore.

Despite having a higher population density, Mandya taluk ranks fourth in terms of area, covering 699.06 square kilometres. Srirangapatna, on the other hand, has the smallest area, accounting for only 6.9% of the district's total area.

Objective

The present paper attempted to study the irritation intensity in Mandya district, Karnataka.

Methodology

In order to conduct a thorough investigation, I reviewed a large body of existing literature on water resource utilization, irrigation methods, and disparities within comparable geographic regions. My focus was on the Mandya District in South India, a region chosen for its importance in terms of water resource imbalances and diverse irrigation practices. I traced the evolution of water management in Mandya District using historical documents, research papers, and governmental reports. Supplementary data was obtained from the Government of Karnataka's Directorate of Economics and Statistics, which provided critical historical records of irrigation sources and trends. I assessed changes in net irrigated area using statistical analyses for the years 1991, 2001, and 2017, using percentages to identify shifts in the dominance of specific irrigation methods. I investigated specific instances of water resource utilisation within Mandya District using a case study approach, delving into local contexts, socioeconomic factors, and infrastructure development nuances. The findings were systematically compared to historical data, revealing insights into changes in irrigation methods, areas covered, and the overall landscape of water resource utilisation in the Mandya District. In the present study researcher has used the second method to express the intensity of irrigation in the region. Here the intensity has been calculated with the help of following formula.

$$\text{Intensity of irrigation} = \frac{\text{Net irrigated area}}{\text{Net sown area}} \times 100$$

Result and Discussion

The present study reveals that the variation in the intensity of irrigation. **Table-**1 and 2 explain that the Mandya district has about 41.4% of irrigation intensity in the year 1991 and it has been increased to 43.2% in the year 2001, further it has increased to 75.7% in 2017 (**Fig.** 1 and **Table-**2). The analyzing of spatial pattern of intensity of irrigation in Mandya district shown in **Table-**2 there is a significant change has been observed in the intensity of irrigation in the region from 1991-2017,

Source: Computed by Authors

the taluk wise analysis reveals that in 1991 Srirangapattana (63.8%) taluk have recorded high (More than 60%) intensity of irrigation. The medium irrigation intensity (30%-60%) is noticed Mandya (55.9%), Maddur (50.6%), Malavalli (43.7%), K.R. Pet (43.3%) taluks of the region. The taluks like Nagamangala (7.3%) and Pandavapura (29.1%) fall in low intensity of irrigation (less than 30%). The taluk wise analysis reveals that in 2001 Mandya (68.6%) taluk have recorded high (More than 60%) intensity of irrigation. The medium irrigation intensity (30%-60%) is noticed Srirangapattana (59.8%), Maddur (56.7%), Malavalli (42.4%), K.R. Pet (41.6%) and Pandavapura (39.6%) taluks of the region. The Nagamangala taluk (10.2%) fall in low intensity of irrigation (less than 30%) (**Fig.** 1). The taluk wise analysis reveals that in 2017 Mandya (84.6%), Malavalli (70.3%), Srirangapattana (69.4%), Maddur (69.3%), Pandavapura (66.7%), K.R. Pet (61.9%) taluks have recorded high (More than 60%) intensity of irrigation and Nagamangala taluk (21.3%) fall in low intensity of irrigation (less than 30%). In the study period there is positive change in irrigation intensity. It is because of the progress in the construction of new canals to provide water for tank irrigation and every year more and more cultivable areas are brought under cultivation and also increased number of well irrigation and advanced agriculture due to development

of transportation facility. During the study period (1991-2017) the district as whole has shown a significant change in the intensity of irrigation. These taluks have shown a positive change in the intensity of irrigation. It is clear that during the year 1991 the irrigation intensity was about 41.4% and it increased to 75.7% in 2017. The net increase in the volume of intensity of irrigation was about 34.3%. The taluk wise changes in the intensity of irrigation during the study period depicts that only Pandavapura taluk have shown high percentage of change i.e., 37.6%, Srirangapattana taluk have shown less change in intensity of irrigation i.e., 5.6%.

Taluka wise Analysis

The intensity of irrigation in Mandya district increased from 41.4% in 1991 to 43.2% in 2001 and further to 75.7% in 2017. The spatial pattern analysis indicates a significant change in irrigation intensity from 1991 to 2017. In 1991, Srirangapattana taluk had the highest intensity of irrigation (63.8%), classified as high. Mandya, Maddur, Malavalli, and K.R. Pet taluks had medium intensity (30%-60%). Nagamangala and Pandavapura taluks had low intensity (less than 30%). In 2001, Mandya taluk now has the highest intensity (68.6%). Srirangapattana, Maddur, Malavalli, K.R. Pet, and Pandavapura taluks had medium intensity. Nagamangala taluk remained in low intensity. In 2017, Mandya, Malavalli, Srirangapattana, Maddur, Pandavapura, and K.R. Pet taluks recorded high intensity. Nagamangala taluk remained in low intensity. Positive changes in irrigation intensity are attributed to the construction of new canals, increased cultivable areas, well irrigation, and advanced agriculture facilitated by improved transportation. (**Fig.** 1) The overall district experienced a significant increase in irrigation intensity from 41.4% to 75.7% during 1991-2017, representing a net increase of 34.3%. Pandavapura taluk showed the highest percentage change (37.6%). Srirangapattana taluk showed the least change in irrigation intensity (5.6%).

Conclusion

Despite being irrigated by two commands, Mandya district has 1.46 lakh ha fully dependent on rainfall. The crop productivity in such areas is limited to dry crops like ragi, horsegram, avare, maize, groundnut etc. Irrigated area predominantly grows paddy and sugarcane. Irrigated farmers invariably record higher incomes, while farmers from dry areas continue to reel under poverty. The inequality of growth rate in income of these two distinctly different areas has not been able to be neutralised by any other sources of irrigation, including well irrigation. Mandya district has only 5000 ha under bore well irrigation, while open wells irrigate around 6800 ha.

However, there is excellent scope to harvest rain water in smaller structures like farm ponds, check dams, nala bunds and other water shed structures in un-irrigated areas. The present district irrigation plan focuses on use of rain water more efficiently by various water shed structures for protective irrigation as a measure of drought mitigation. Further, nearly 630 tanks are available in Mandya district. They have created irrigation potentiality of around 16000 ha. But, there is need to utilise this tank irrigated area, by effective measures like tank desilting, renovation or filling tanks with canal/ lift irrigation schemes. There is general lacuna in utilizing the canal water, in terms of efficiency. Most distributaries/ field channels unlined and there is vast scope to improve the irrigation efficiency by proper lining to these structures, and attending to other canal maintenance works timely. This way, the created potential can be utilized fully. All these aspects are considered, while Mandya district Irrigation Plan is developed- with the ultimate objective of utilizing the created potential with expansion, wherever possible irrigated area and drought mitigation in non- command areas. A new cropping pattern involving regulated sugarcane cultivation and reducing other water intensive crops can save large quantity of water and this can ensure water availability to tail end areas.

WORKFORCE ASSESSMENT OF PRINCIPAL EMPLOYEES AND AGRICULTURAL WORKERS IN KANNAUJ DISTRICT, UTTAR PRADESH

Kalpana Devi and Dr. Shashi Bala Singh

Abstract

The research focuses on assessing the workforce dynamics within Kannauj district for the year 2021-22, emphasizing the distribution and prevalence of principal employees and agricultural workers across its development blocks. The study examines the proportions of principal employees in comparison to the total population in various blocks. Umaruda and Gugarapur exhibit notably high percentages, signifying substantial principal employment, followed by Talgram with a significant figure. Haseran and Jalalabad portray a slightly lower ratio, while Kannauj, Saurikh, and Chhibramau demonstrate relatively comparable patterns. These percentages elucidate the distribution and concentration of principal employees, showcasing varying proportional representations among the development blocks. Moreover, the study investigates the proportions of agricultural workers within the total principal employee workforce across the district. Areas like Saurikh, Haseran, and Chhibramau showcase high percentages of agricultural workers among the principal employees, indicating significant agricultural employment. Umaruda and Kannauj also demonstrate substantial agricultural labour presence, while Gugarapur shows a slightly lower ratio. Talgram and Jalalabad exhibit relatively fewer agricultural workers compared to the total principal employees in those specific blocks. These percentages offer insights into the distribution and concentration of agricultural workers concerning the total principal workforce across different development blocks in the Kannauj district, reflecting distinct levels of agricultural employment across these regions during the specified period. The study utilized data sourced from official government records, statistical reports, and surveys conducted by relevant authorities, encompassing population figures, principal employee counts, and specific employment statistics for agricultural workers. The research aims to depict variations in employment patterns and workforce concentrations, focusing on the proportional representations of principal employees and agricultural workers across the district's diverse blocks during the specified period.

Introduction

Kannauj district in the year 2021-22 witnessed varied proportions of principal employees and agricultural workers dispersed across its distinctive development blocks, portraying notable employment diversities. This study scrutinizes the intricate dynamics of workforce distribution within the district, focusing on the prevalence of principal employees and agricultural workers across different regions. The analysis reveals significant disparities in the proportion of principal employees concerning the entire population across various development blocks. Umaruda emerges as a frontrunner, boasting the highest percentage of principal employees at 27.44%, closely shadowed by Gugarapur at 27.07% and Talgram at 26.59%. Contrastingly, Haseran, Jalalabad, Kannauj, Saurikh, and Chhibramau exhibit relatively lower percentages, portraying a discernibly varied distribution of principal workers within these areas. Moreover, the study unveils an intriguing variation in the proportion of agricultural workers relative to the total principal employee workforce across the district's development blocks. Saurikh, Haseran, and Chhibramau stand out with notably high percentages of agricultural workers among the principal employees, ranging from 84.74% to 84.13%. Umaruda and Kannauj display substantial agricultural labour presence, whereas Gugarapur, Talgram, and Jalalabad depict relatively lower ratios of agricultural workers compared to the total principal employees in their respective blocks. This research draws upon comprehensive data sourced from official government records, statistical reports, and surveys conducted by relevant authorities. Employing a meticulous methodology involving precise demographic data collection, and cross-referencing of population figures with employment records identified principal employees across development blocks. Additionally, statistical calculations discerned the distribution and concentration of agricultural labour within the principal employee workforce across diverse areas within the Kannauj district.

Objectives

(1) The primary objective is to analyze the distribution of principal employees across different development blocks within Kannauj district during 2021-22.

(2) To examine the variation in the proportion of agricultural workers relative to the total principal workforce across different development blocks.

Database and Methodology

The data used for analyzing the distribution of principal employees and agricultural workers in the Kannauj district for the year 2021-22 was sourced from

official government records, statistical reports, and surveys conducted by relevant authorities. This data includes information on the total population figures, the count of principal employees in various development blocks, and the corresponding employment statistics specific to agricultural workers. The methodology involved collecting accurate demographic data from the census and employment records for the Kannauj district. The total population figures were cross- referenced with employment records to identify principal employees in different development blocks. The percentage of principal employees relative to the entire population was calculated for each block to ascertain their proportional representation. Analyze agricultural employment, the total count of agricultural workers within the principal employee category was identified based on official records. The percentage of agricultural workers concerning the total principal employees in each development block was computed to discern the distribution and concentration of agricultural labor across various areas within the district. This analysis involved statistical calculations, ratios, and percentage computations to understand the representation of principal employees and agricultural workers concerning the total population and the total principal employee workforce, respectively. The study aimed to depict variations in employment patterns and workforce concentration across the diverse development blocks within the Kannauj district for the specified period.

Results and Discussions

Principal Employees

In the Kannauj district for the year 2021-22, the percentage of total principal employees about the entire population varies across its development blocks. Among these blocks, Umaruda stands out with the highest percentage, comprising 27.44% of principal employees. Compared to the overall populace. Gugarapur closely follows with 27.07%, demonstrating a significant presence of principal workers within its boundaries (**Table-**1 and **Fig. 1**). Talgram maintains a substantial figure at 26.59%, indicating a considerable proportion of principal employees relative to the population. As we move further, Haseran and Jalalabad exhibit 24.5% and 24.32% percentages, signifying a noticeable but slightly lower ratio of principal workers compared to the total population. The district's administrative centre, Kannauj, registers a percentage of 23.87%, suggesting a slightly lower presence of principal employees concerning the overall populace (**Fig. 1** and 2). Overall, these percentages delineate the distribution and concentration of principal workers across the development blocks within the Kannauj district, portraying variations in their proportional representation concerning the total population for the specified period.

Agricultural Workers

In the Kannauj district for the year 2021-22, the percentage of total agricultural workers in comparison to the total principal employees varies across its development blocks. The blocks of Saurikh, Haseran, and Chhibramau exhibit the highest percentages, with 84.74%, 84.55%, and 84.13% respectively. This indicates a significant portion of agricultural workers about the total principal workforce within these areas. Umaruda and Kannauj showcase percentages of 83.71% and 83.69% respectively, signifying a substantial presence of agricultural workers among the principal employees within these blocks. Gugarapur, with a percentage of 79.96%, with the highest percentage of principal employees at 27.44%, indicating a significant presence of this workforce category in comparison to the total population. Gugarapur and Talgram followed closely, showcasing noteworthy figures of 27.07% and 26.59% respectively, underlining substantial concentrations of principal employees in these regions. Haseran, Jalalabad, Kannauj, Saurikh, and Chhibramau exhibited percentages ranging from 23.62% to 24.5%, depicting a lower but noticeable representation of principal employees relative to the overall populace. The findings demonstrate varying degrees of proportional representation of principal workers across the development blocks, signifying localized employment patterns within the district. Saurikh, Haseran, and Chhibramau emerged as areas with the highest percentages of agricultural workers among the total principal employees, ranging from 84.13% to 84.74%. This signifies a predominant agricultural workforce in these regions. Umaruda and Kannauj exhibited substantial proportions of agricultural workers at 83.71% and 83.69% respectively indicating a significant presence of agricultural labour within the principal employee category. Gugarapur displayed a considerable but slightly lower ratio of agricultural workers at 79.96% compared to the total principal employees,

showcasing a moderate agricultural employment level. Talgram and Jalalabad depicted relatively lower proportions of agricultural workers at 77.62% and 75.86%. Overall, these findings provide valuable insights into the employment patterns and the prominence of principal employees and agricultural workers across diverse development blocks within the Kannauj district, shedding light on the multifaceted nature of employment dynamics within the region.

Conclusion

In conclusion, the analysis of principal employees and agricultural workers across the development blocks within the Kannauj district for the year 2021-22 offers valuable insights into the employment landscape of the region. The findings highlight distinctive patterns in the distribution and concentration of principal employees and agricultural workers, underscoring the variations in their proportional representation concerning the total population and the total principal employee workforce. The examination of principal employees revealed significant disparities across development blocks, with Umaruda, Gugarapur, and Talgram recording notably higher percentages compared to other areas. These figures depict areas with substantial employment in non-agricultural sectors, suggesting a potentially diverse employment landscape with varying opportunities in industries beyond agriculture. Understanding the dynamics of principal employees and agricultural workers across different blocks is crucial for informed policy formulation and resource allocation, aiming to address regional disparities, promote inclusive growth, and enhance overall socio-economic development within the Kannauj district. Further research and ongoing monitoring of employment patterns will be vital to track changes, identify emerging trends, and implement strategies that foster balanced and inclusive development across the region's diverse socio- economic landscape.

DYNAMICS OF ELECTORAL BEHAVIOR OF PANCHAYAT ELECTION IN NADIA DISTRICT, WEST BENGAL

Dr. Nizamuddian Khan, Dr. Firoj Biswas and Dr. Mostafijur Rahaman

Abstract

The present study investigates the events and circumstances that shape the voter's decisions and their involvement in the electoral process. It also aims to analyze factors that have affected electoral politics and voting behavior in the Nadia District Panchayat election. India's geo-political, socio-economic, cultural, and religious conditions played an important role in the formation, identity, and growth of the political parties in West Bengal. The present study deals with the comparative analysis of the major political organizations and their role in future political developments in the province. This research article also provides a deep political insight into the nature and quality invested in the leadership of the West Bengal political parties. The paper analyzes the analytical overview of Nadia's electoral politics from the 2008 to 2018 Panchayat elections. The study examines the causes of the Trinamool Congress's landslide victory in the Nadia district elections and why residents overwhelmingly voted for the Maa Mati Manus model of development promised by the party in the state's Panchayat election. The present study is based on both Primary and secondary data sources and adapted the qualitative and quantitative methods. The fundamental approaches include participatory research methods, narratives, discourses, and grounded theory. The data has been analyzed and interpreted with the help of various statistical methods like Factor Analysis, Correlation, and cartographic techniques for analyzing data like percentages, choropleth, line Graphs, and Arc GIS 10.2. It is being observed that political party-based association, local groupings, language, class, factors of caste, social welfare policy, ideology, and religious identities are the main contributing factors in defining the trend of voting behavior in Nadia District, West Bengal.

Introduction

Democracy embodies public participation and people empowerment necessary to address the power inequities in social, economic, and political spheres

(Bandyopadhyay, 2012). It affects real change in society. Democratic participation of the grassroots in policy formulation and execution is necessary to bridge the gap between the people and the policy-makers at the highest levels (Dasgupta 2020). The decentralization of state power is essential to ensure developing societies' democratization (Biswas & Mondal 2019). Therefore, the Panchayat election is an integral part of the decentralization and democratization process in the rural areas of India. The village Panchayat existed even before independence, but they were unofficial, informal bodies without significant power. After independence, reference to the village Panchayat in the Directive Principles of State Policy of the Indian Constitution did not give much leeway to Panchayat formation in the country. "The states shall take steps to create village Panchayat and invest them with such rights and authority as necessary to allow them to function as self-government units," the Indian Constitution's Article 40 declared. Long after the adoption of the Indian Constitution, the Panchayats were recognized as an important political tool for involving the vast majority of the rural population in public policy-making at the grassroots level. The idea of the Panchayati Raj system has been prescribed in the preamble of our constitution, which speaks about the right of liberty of thought, expression, belief, faith and worship, equality of status and opportunity, fraternity, as well as to participate in all types of functions and to have faith in any religion (Banerjee, 2012).

Local government strengthens the foundation of democracy. It links people at the grass-root level and the central or state level. The basic idea behind the formation of Local Government is people's participation in their day-to-day developmental activities. But elections are examined from various angles, including political, social, cultural, and geographic ones. A politically organized community's socio-cultural aspiration is reflected in its elections. Caste and religion are the main variables affecting voters' political participation and casting their ballots. Caste issues, however, have largely taken control of political participation in Indian states after the Mandal Commission Report's 1991 recommendations (Jeffrey & Young, 2012), most notably in northern states. Though linked with the electoral politics in the West Bengal political space, it can be claimed that as a social space, Bengal has a very different political and cultural ethos rooted in the identity of place. From the very perspective of humanistic geography through phenomenological inquiries, the place and lived experiences of "beings" largely control the "subjectivity" of electoral responses. Bengal can be adjusted to this theoretical frame of place connections because of its specific genre. However, political movements like the Renaissance,

social reform, and the communist-peasant movement further enhanced the state's political value on the phenomenological–existential ground—the persistence of social movements caused normative standardization and politicized this particular place (Biswas et al 2018). The Left Front government has fostered an environment where caste and religious politics are no longer valid, in line with the Marxist theoretical framework that only applies to superstructure (Bandyopadhyay, 2012). When the Left Front lost its majority in the Panchayat election for the first time since 1975, West Bengal politics underwent a significant upheaval. The primary supporters of the left, such as landless and marginal landowners, Scheduled Castes (SC), and Scheduled Tribes, are becoming more anti-incumbent due to increased accountability constraints brought on by changes in voter characteristics and more substantial governance failures. New youthful voters, aggressive anti-incumbency, and the Nandigram and Singur issue significantly altered West Bengal's political scene (Chatterjee, 2018), and the Nadia district was no exception. Hence, the long-term regime of the left front subsided the caste issue in electoral politics in Bengal. However, "class" was a key component of social stratification during the communist regime. Class constitutes the central focal theme in political discourse. The concept of "class" offers a contemporary foundation for political parties founded on Marxism.

However, it is believed that the left's demise has allowed identity politics; significantly, caste and religious identities are centrally involved in post-communist West Bengal electoral politics. Combined efforts of Abdur Razzak Mollah, a former member of the Communist Party of India (Marxist) CPI (M) and current minister of the AITMC and Matua Mahasangha helped Mamata Banerjee win the 2013 and 2018 Panchayat elections (Biswas et al 2022). In 2018, the Bhartiya Janata Party (BJP) structured planned electoral mobilization techniques to mobilize the Hindu voters in West Bengal (Palshikar, 2015). Additionally, the BJP, led by Narendra Modi, made a conscious effort to intermix pan-national identity, nationalism, and economic developmental issues (Shastri, 2019). He nurtured the idea that nationalism is correlated to Hindutva's national frame. Developmental issues were a fundamental drive within the electoral principles. The BJP's success in the 2018 Panchayat elections is notable for the geographic scope of its triumph, the increase in vote share, its capacity to convert votes into seats, and the broad socio-economic coalition that made this victory possible. However, recent observations of the Nadia district's political culture have revealed several traits. The communal versus non-communal fault line is one of the most important political fault lines in West Bengal.

The "communal" viewpoint frequently asserts that India's nationhood is founded on the Hindu community's cultural, religious, and ethical practices. The non-communal perspective, in contrast, holds that India's nationalism is not based on any particular community or culture. The socio-cultural existence of India is increasingly complicated and pluralistic as a result. The dominance of regional parties and the continued rise of national parties are reflected in how Nadia politics have changed over the past ten years. However, in recent years, caste and religious affiliation have been important factors in the Nadia election. Power-driven identity politics damage the ideal of democracy and draw attention away from other socio-economic problems, including unemployment, poverty, crime, corruption, the safety of women, and farmer suffering. Caste, class, and community divisions sometimes result in political violence, conflict, and tensions.

Objective

The main objective is to examine the factors that influence the voting behavior of the people in the Nadia District of West Bengal.

Database and Methodology

The present study based on both the arm of research primary and secondary source of data. The primary data constituted the significant input for the study. Primary data was collected from voters through a field survey. For that, a total of 500 voters have been selected from twenty Panchayat segments of Nadia district. In addition, direct field observations and a focus group discussion (FGD) have also been carried out to supplement the survey data. Qualitative methods and approaches are this research work's dominating tools and techniques. Participatory research methods, narratives, discourses, and grounded theory are the fundamental approaches for this study. It analyses the grounded theory of cultural space and place's identity influencing electoral behavior and its variations across the state. The study is also based on historical and analytical methods. The historical method helps understand the past experiences of electoral behavior of certain issues and challenges pertaining to voting behavior and party performances in Nadia District, West Bengal. This study is based upon secondary data sources collected from the Election Commission of India, New Delhi. The data has been analyzed and interpreted with the help of various statistical and cartographic tools and techniques like percentage. The Newspaper report, election documents, and manifesto are the archival sources consulted to explain political parties' role in the electoral campaigns and mobilization.

Results and Discussions

Electoral Politics in West Bengal with Special Reference to Nadia District

As a social space, Nadia District has produced a distinct political culture since the historical memoir. The meaning of place intrinsically nurtured its cultural evolution. Monarchical and feudal regimes have significantly influenced the political history of Nadia District in addition to democratic civic administration (Sinharay, 2012). However, the extreme political socialization of the residents of Nadia District, who predominantly reside in rural areas, largely governs the district's electoral dynamics. The people are controlled by the levels of social stratification based on caste and class identities. People will not be free but respond as members of a particular social group (McMillan 2012). Political parties use voters' cognitive frames for their electoral mobilization in this social context. However, the recent elections in West Bengal, where populist inclinations attempted to supplant the pre-existing political environment, were influenced by general influences of "waive elections" and their characteristics. Media, propaganda, and other outside entities work to instill their justification in voters' minds as "bio colonization" tools. A few political parties are trying to erode caste distinctions and make them more fluid to influence voters more broadly. Political parties make an effort to participate in accommodation politics.

They form alliances and use their identities to mobilize voters and win elections (Nath & Ray, 2022). However, religion has become a significant factor in controlling voters' imaginations and voting behavior in Bengal. Religion is one of the most important factors that can quickly mobilize a wider range of demographic compositions (Hasan 2010). Religion and caste are important tools to mobilize voters and win elections in the Nadia District. This particular emotion develops the environment of "self and other selves," "binary structuralism," and "bipolar religious order of society." Social feelings and already-existing social order serve as a ready-made canvas for political parties' electoral campaigns (Jungherr 2016). The Nadia District elections served as an important case study for empirical research on the effects of various socio-economic instruments on electoral politics. In this context, it is viable to feature these elements and their consistent impact on elections. Therefore, this study investigates the role of caste, class, religion, historical memories, iconization, and populism in the Panchayat election of the Nadia district. The political culture of the Nadia district is significantly different from that of the rest of the state. Caste and religion were declared invalid by the left-front government. Marxists are the proper form of social organization since it

offers a current framework for categorizing, organizing, and mobilizing individuals (Chakrabarty 2017). In the decline of the left as a significant force in the district, caste played an important role. In the politics of postcolonial West Bengal, no doubt left culture has produced the sense of ideological essence of electoral politics. However, caste-based identity politics has transformed the values of left politics in the state. It is a fact that caste played a significant role in Nadia district's Panchayat elections. The Matua Mahasangha's growing affiliation and support with BJP, a mainstream political party. Abdur Razzak Mollah's recent efforts to forge a united political front of Dalits and Muslims (Sinharay 2019). Although most of the left-front leadership in Bengal comes from the upper castes, the communists have always enjoyed unwavering support from the Dalits. The Dalits have never felt the need for their independent political platform. The left front's apparent awareness of his demise creates a favorable environment for identity politics. In such circumstances, West Bengal will unquestionably see a rise in identity-based political mobilization. The past election witnessed a bipolar contest between the CPIM and the AITMC.

However, the last two elections have seen the emergence of the BJP as a significant political force in Nadia district politics. The BJP performed very well in the 2013 and 2018 Panchayat elections. The inherent values of imagined identities nurtured the cognitive environment of individual voters. However, identity associations on the emotional line are short-lived and challenged by the existential reality and rooted intentionality of "self" performing in individuals as electorates (Bondi 2004, Fukuyama 2018). Caste, community, clan, and kinship are the identities drastically involved in elections for large-scale political mobilization. These variants undermine the ideal democratic spirit and divert focus from other "realistic" socio-economic issues like poverty, unemployment, crime, corruption, women's security, and farmer unhappiness. The politics of daily life geography raises political questions as emerging disparities based on caste, class, and community. It may occasionally lead to hate, conflict, and even violence. Instead, regionalism and the multi-party system have created a new political environment where voter expectations are evaluated following variances in voter consciousness and information flows (Biswas, 2022). The decline of Congress and CPIM created an atmosphere for the Bhartiya Janata Party (BJP) in the Nadia district of Bengal politics.

Electoral Trends and Performance of Political Parties in Nadia District Panchayat Election from (2008- 2018)

Our study deals with the spatial and temporal variations of electoral behavior in the three Panchayat elections in the political space of Nadia district, West Bengal.

It covers the elections of 2008, 2013, and 2018. The primary focus of the study is to identify, describe, and analyze the participation patterns and associated parameters with the help of electoral data, maps, and empirical observations. The electoral seat of a political party in the legislature reflects its relative strength and determines which party will form the government. The percentage of seats won and overall seats contested is used to measure a political party's level of success. In comparison to other political parties, Trinamool Congress had the highest success rate in the Panchayat election of 2018, with a score of 67.7 percent. It shows that, under Mamata Banerjee's leadership, Trinamool Congress enhances its electoral value by capturing voters' imaginations at a larger scale, covering a larger segment of social groups. In the 2008 Panchayet election, the Communist Party of India (CPIM) was the leading political party, winning more than 30% of the vote. However, in the 2013 panchayet election, its performance slipped. From the 2008 Panchayat elections to the 2018 Panchayat elections, the Indian National Congress's performance has declined on trends. Voter behavior in the Nadia District observed a paradigm shift from 2008 to the 2018 Panchayat elections. **Table-**1 displays the performances of political parties based on the percentage of seats and votes they got in the 2008, 2013, and 2018 Panchayat elections (**Table-**1).

Table-1: Patterns of Party Performances

Political Party	Patterns of Party Performances					
	2008		2013		2018	
	No of Seats	% of Votes	No of Seats	% of Votes	No of Seats	% of Votes
CPIM	891	28.22	547	22.16	340	16.2
AITMC	809	30.22	1384	39.3	1595	44.79
INC	650	14.3	515	13.12	379	3.61
BJP	205	7.14	385	13.14	759	26.7
CPI	20	3.6	10	1.6	4	0.5
AIFB	37	4.12	27	3.12	15	1.1
SUCI	26	4.7	20	1.8	11	0.8
CPIML	5	1.8	5	0.8	0	0.4
RSP	5	1.2	5	0.5	0	0.3
IND	43	4.7	72	4.46	106	5.6
Total	2691	100	2970	100	3209	100

Source: Based on Statistical Report in West Bengal Panchayat Elections from 2008 to 2018. West Bengal State Election Commission, Kolkata

Table-1 shows the TMC won 809 out of 2691 seats in the 2008 Panchayat election, with a vote percentage of 30.22. It gained 1384 seats out of 2970 in the 2013 election. It shows the increasing tendencies as 1595 seats were positively secured out of 3209 in the 2018 election. It achieved a vote percentage of 44.79 in this election. Compared with the 2013 Panchayat election, AITMC's party performances have improved regarding seats and vote share from 2008 to 2018. With this outcome, Trinamool Congress and Left political organizations dominated most of the political spaces in the Nadia district up to the 2013 Panchayat election. With the widespread criticism of the Leftist government, particularly in light of the Nandigram and Singur crises, the Trinamool Congress established itself in the Nadia district. Later, state politics viewed Mamata Banerjee as an influential leader in the state. In the struggle of Mamata Banerjee against the left, she proved herself to be the true alternative to the opposing voice. She was the only opposition leader who relentlessly opposed the left, which yielded her electoral benefit. Muslims constitute about 23 percent of the votes. Their votes are decisive, constituting 30 percent of the seats in the Nadia district. Trinamool Congress Government gives a monthly stipend of 2500 imams and muezzins. It distributed bicycles to girl students enrolled in madrassas. Provided scholarships for minority students.

Trinamool Congress offered reservations to Muslim OBC and declared Urdu the second language in the Muslim-populated district. Trinamool Congress intact Muslim voters due to the factors mentioned above that gave Trinamool Congress massive electoral victory in the Panchayat elections. The numerous welfare policies initiated by Mamata Banerjee, like the Rupashree Scheme, Kanyashree Scheme, Sabuj Sathi Scheme, Khadya Sathi Scheme, Swasthya Sathi, Imam Bhata, Pandit Bhata, etc., are the most popular schemes that influenced the voters and culminated in the resulting outcome of 2008, 2013 and 2018 Panchayat elections. **Table-**1 shows the 2008 Panchayat election; BJP won 205 out of 2691 seats with a vote percentage of 7.14. It got 385 out of 2970 seats, with a vote percentage of 13.14 percent in the 2013 election, and 759 out of 3209 seats in the 2018 election, with a vote percentage 26.7. In the 2008 Panchayat elections, the Bhartiya Janata Party did not have a significant impact. However, in 2008, left-wing organizations had more influence over a wider range of voters. The Trinamool Congress and the Left Front even balanced the 2013 Panchayat elections. It implies that the Bhartiya Janata Party's arrival strongly impacted the Panchayat elections in the Nadia district in 2013 and 2018. It means that the iconized political spaces have transformed with Narendra Modi's ascent to the position of a national populist leader. In these Panchayat elections, there were considerable differences between the seat and vote shares.

Compared to the 2013 Panchayat election in West Bengal's Nadia district, the BJP's party performance in the 2018 Panchayat election improved in terms of vote and seat share. The charismatic leadership of Narendra Modi, given his Gujarati roots belt, was largely nurtured through dedicated work as a skillful state leader. Hindu voters were not only institutionalized in saffron ideology and remained electorally loyal to Modi but also became the torchbearers of his novel brand of right-wing Hindutva politics. Saffron color comprises three political components: charismatic leadership, the strength of electoral rhetoric, and a vision of transformational governance. This pattern of party performances demonstrates the Trinamool Congress and BJP's intense electoral competition. The BJP has slightly benefited from capturing seats in the Blocks with more Hindu voters. This electoral situation highlights that CPIM, formerly the dominant force in state politics, has a lower voting percentage and likely switched to BJP. In recent elections, votes may have shifted more due to historical conflicts between BJP and AITMC officials and volunteers. The claim is that CPIM has weakened its ideological grip, and its traditional supporters have switched to another political party. The most likely explanation for this phenomenon falls into two categories. First, the CPIM voters have been split into two groups, and they now want the BJP to spread a negative message about the Mamata-led AITMC. Iconized politics, sentiment-based mobilization, and populist politics are other strong factors for the BJP.

The welfare policies that Modi has introduced include Jan Dhan Yojana, one of the largest financial schemes in the world, which opens bank accounts for 30 crore unbanked households, and Kisan Yojana, a direct income support program for the farming community. Awas Yojana, which offered to house 1.5 crore low-income people; Pradhan Mantri Ujjwala Yojana, which installed smoke-free kitchens in 70 million homes; and Swachh Bharat Abhiyan (Clean Bharat), which provided toilets to nearly ten crore people, were other significant programs (Heath & Tillin 2018). Gujarati Model and Narendra Modi's charismatic leadership is important in mobilizing ground-level leaders and voters. Hindu voters stayed electorally loyal to Modi, institutionalized the saffron ideology, and took up the mantle of his innovative form of right-wing Hindutva politics (Dasgupta 2020). The BJP criticized the Trinamool Congress for allegedly favoring Muslims. 'Nation First, national security, zero-tolerance approach to terrorism, the welfare of soldiers, battling infiltration, implementing the Citizenship (Amendment) Bill, combating left-wing extremism, Ram Mandir, Jammu & Kashmir - Article 370' were some of the key themes of Modi's populist campaign. **Table-**1 shows that in the Panchayat

elections of 2008, CPIM won 891 out of 2691 seats, with a vote percentage of 28.22; in the elections of 2013, it got 547 out of 2970, with a vote percentage of 22.16; and in the election of 2018, it occupied the 340 out of 3209 seats having vote percentage of 16.2. Compared to the 2008 Panchayat election in Nadia district, there is a declining pattern of party performance for CPIM in the 2013 and 2018 Panchayat elections regarding vote share and seat share. The CPI(M) cultivates a powerful organization with a broad network to keep a firm hold on the cadres and voters. As a result, Chief Minister Buddhadeb Bhattacharya created the new slogan, "Agriculture is our base, industry our future" (Jaffrelot & Verniers 2020). After acquiring agricultural plots from small farmers and landowners, he zipped across the state, setting the cornerstones for new townships, food parks, industrial units, shopping malls, and catering training facilities. The Left Front Government in West Bengal had created a positive and healthy environment in the industrial sector. The electoral success of the Left Front cannot be explained by economic parameters alone. The fact that the CPIM is a disciplined political party should be kept in mind in understanding the dynamics of power relations in West Bengal. Party discipline facilitates a strong link between the party leadership and the cadres.

This enables the leadership to translate effective organizational goals into grassroots action. The active involvement of the party cadres in the people's everyday life gives the CPIM strategic advantages in election campaigns. In the urban areas, the party maintains mass contact through the local committees and 'Mahila Samiti (Ghosh 2022). The Panchayati Raj revolutionized rural Bengal's economy and created a significant market for industrial goods during the Left regime in the state. The favorable industrial environment strengthened the Left Front Government. It triumphed in the 2008 Panchayat elections. Rising voter unhappiness with local incumbents on corruption, health, education provision, and other local public goods like roads and irrigation are examples of Left Front governance failures. Other programs include private benefit schemes like the Mahatma Gandhi program for drinking water, ration cards, bank loans, agricultural micro kits, old-age pensions, and the Indira Awas Yojana. Failures of state-wide programs, such as the stagnation of employment in rural areas, the inability to contain inflation, and issues with the Left Front's land acquisition practices close to Singur and Nandigram, might be attributed to non-local leaders. All of these problems, taken together, impacted the performance of the left front in the 2013 and 2018 Panchayat elections (Nath & Ray, 2022). The absence of left political force in the state and among the rural masses projects the historical visualization of its emergence in 1977.

Left Front government emerged, riding the wave of anti-Congress mass resentment. In the initial years, it undertook some popular measures like distributing vested lands among the landless, registering the names of the sharecroppers under Operation Barga, and reviving the Panchayati Raj institutions. At the same time, these democratic reforms helped consolidate the new communist party in the rural areas. However, undemocratic measures were followed later to eliminate opposition forces from the countryside. CPIM Neglected the voice of opposition to devalue and suppress the inherent identity forces that led to the decay of left rule even in the rural areas of West Bengal. In this regard, the Left Front rule that systematically and meticulously tried to direct consolidation as a dominating single party, even at the expense of all opposition parties, even junior partners, particularly in rural Bengal, has become irrelevant in electoral mobilization. **Table-**1 shows that in the 2008 Panchayat election, INC won 650 out. During the 2013 elections, INC won 515 out of 2970 seats with a vote percentage of 13.12; in the 2018 election, it won 379 out of 3209 seats with a vote percentage of 3.61. Comparing the 2008 Panchayat election in the Nadia district to the 2018 Panchayat election, there is a declining pattern of INC party performance regarding vote share and seat share. As a result, the INC party's performance has suffered as voters from the upper caste, Dalits, and Muslims have stopped supporting it. The majority of those who vote for Congress are from socially and economically disadvantaged groups. However, AITMC, which speaks directly to these communities, poses a real threat to Congress in the race for their votes.

The identity of the Dalit was historically less politicized. CPIM and Congress both had mileage in the reserved category voting performance, according to behaviors drawn from past electoral behavior of electorates in the Nadia district of West Bengal. It is because voting behavior's class-based orientation overshadowed caste-based mobilization or politics of identities. However, the recent Panchayat elections in 2018 showed the emergence of caste-based identity politics, as the BJP chose a Dalit as its state president. The Nadia district has been using the state president's identity. However, the deterioration of left politics in the state and rural West Bengal also destroyed the ideological essence of West Bengal politics. The ways of electoral mobilization consequently transformed into a pragmatic turn. The issues of labor and class identity-based mobilization are deformed into religion, caste, and identity politics. The features of national identity and issues and national tendencies overshadowed the regional identity of place and local social questions. The instrumental agencies like media and populism drastically shaped the authentic

political voices of rural society. The politics in West Bengal observed a drastic change and transformation from the Left-based political constructs to the emergence of Trinamool as a powerful political voice in the state. The changing demography and political situations are the vital cause of this transformation. Rising population growth, demographic fragmentation, middle-class dissatisfaction, and social and economic detachment are the general factors in the change of political regime.

Caste and Voting

The caste system largely affects the electoral campaign in rural areas, where caste and Baradari (Kinship) loyalty is seen as one of the most decisive factors determining the voting behavior of the villagers (Bandyopadhyay, 2012). In the Nadia district, individuals simultaneously hold multiple ethnic identities of language, religion, politicized umbrella caste categories (such as Upper Castes, Backward Castes, and Scheduled Castes), and highly localized sub-caste/kinship groups biradari or jati. Ethnicity matters in voting behavior and depends on the differences in the economic well-being of ethnic groups in a system (**Table-**2). When some ethnic groups are wealthy and others are poor, the silence of ethnicity in politics should increase. BJP's propaganda invites all majority community members to look at themselves as Hindu first and members of some caste groups second because of the socio-economic differentiation in the society. In a caste group, the richer people were more pro-BJP; they tended to be because of caste and class (mainly because of the party's reservations vis-à-vis caste-based quotas). It is still valid, but some changes have occurred in the context of post-1991 liberalization. Respondents believe Trinamool Congress got full majority support from the minority community (**Table-**2).

Table-2: Caste and Voting Preference of Respondents

Category	Voting Preference of the Political Party (%)			
	AITMC	BJP	Left	Others
General	35	40	20	5
OBC	40	35	18	7
SC	35	45	15	5
ST	30	50	15	5
Minority	82	3	10	5

Factors Influencing Voting Behavior

A number of factors influence an individual's voting behavior. It is mainly determined by race, religion, caste, community, region, language, charismatic leadership, ideology, local issues, political wave, etc. Thus, an attempt has been made to determine the sources of voting behavior (**Table-**3).

Table-3: Distribution of Respondents According to Factors Influencing Voting Behaviour

Factors affecting Voting Behaviour	Number of Respondents	Percentage
The ideology of the Party	100	12.7
Programmes and Policies of the Party	160	15.88
Personality of the Candidate	140	7.94
Religious Consciousness	400	22.22
Caste Consciousness	250	17.46
Local issues of Electricity, Road, and Water	140	15.87
Any Other	10	7.93
Total	1200	100

Source: Field Survey, 2020-21

The reason is that Muslims see the BJP as a party threatening their interests. BJP has successfully increased its popularity among SC/ST community voters with the help of pro-poor policies like the Ujjala Yojana, Pradhan Mantri Awas Yojana, Swatch Bharat Mission free toilet, Free Ration, and CAA/NRC Issues. **Table-**3 displays that the majority of respondents, i.e., 22.22%, gave importance to 'religious consciousnesses in deciding on whom to vote for in the election, while 17.46% of respondents emphasized caste consciousness and 19.20% of respondents emphasized 'local issues of electricity, road, and water of electricity. Other factors viz., 'programs and policies of the party,' 'ideology of the party had received preference of the electorates at the rate of 12.70%. It shows that religion and caste is the most important factor in voting behavior in Nadia district voters. The candidate's personality has minimal influence on the voting decisions of the region's people. Apart from these factors, priority has also been given to other factors like political parties' leadership and their representative's work or performance while voting. Therefore, it is essential to study the voters' preferences regarding political parties' leadership and their representative's work. Considering that the respondents' questions were asked, their opinions are classified below.

Conclusion

Trinamool Congress is becoming increasingly popular in Nadia district, West Bengal. BJP's political performance is a little better where the proportions of Hindu and Matua populations are high. It is a party with a strong ideological foundation that may appeal to the masses of one particular religion. On the other hand, the mutual political rivalries between CPIM and Trinamool congress voters also caused the massive success of the BJP in the Nadia district. The traditional vote banks of CPIM have also transformed their vote and support in favor of the BJP to degrade Trinamool, which has covered the voting scale in the political space of West Bengal. The leadership's quality is still a factor for the Muslim electorate. In regions where Muslims predominate, all major political parties often choose a Muslim as their candidate. They support those parties that promise them more security, respect, and identity. It provides them structurally a wide range of protection. CPIM and AITMC use Muslims as an electoral support base in their respective era of influence. Strategically, both parties succeeded in creating fear and threat of the BJP and rising communalization in the state. Although caste, class, and religion are significant factors in elections and maintaining strong control over people's perceptions. It functioned by identities in general and caste politics in particular. In the Nadia District, these imagined identity variables are particularly crucial and visible in electoral behavior and mobilization in the rural Nadia district. The CPIM has sustained its pro-poor policies for a longer duration. Its policies always benefited the scheduled castes, the Scheduled tribes, and the Muslims in Nadia district, West Bengal. It provided CPIM the power hold for the long term. So, the result revealed that the Trinamool Congress has the more prominent mass acceptance in the Nadia district Panchayat elections. Consequently, an electoral pattern indicates the ideological shifting in order from Left to Centre and now emerging trends of right in the Nadia district.

The politics in West Bengal observed a drastic change and transformation from the Left-based political constructs to the emergence of Trinamool as a significant political voice in the state. The changing demography and political situations are the vital cause of this transformation. Rising population growth, demographic fragmentation, middle-class dissatisfaction, social and economic detachment are the general factors in the political regime change. The emergence of the new middle class in the West Bengal demographic scene caused the degradation of voting influences of left parties. Remarkably, the left's support base was diminished with a long-time sustained problem, including a lack of industry, job opportunities,

and declining health and educational systems in the state. Overall, the civic memories and rise of Mamta Banerjee at a populist scale further challenged the CPIM space among the common masses. The left found the issue of land acquisition in Singur and Nandigram too expensive. In the Nadia district of West Bengal, Most SCs and STs voted for the left until it benefitted their caste interests. The left's policies, such as Land Reform and Panchayati Raj, offered the lower castes a sense of social advancement. It gave them political power at the local level and protected them from the powerful upper-caste landowner class. As a result, the left continued to get support up to the 2008 Panchayat elections. Even after the thirty years of rule by the left parties, the caste and religious consciousness was inherently located among the mindset of electorates. The religious sentiment of social groups was not changed into class consciousness. Economic diversification was not achieved, and the left regime did not address unemployment issues. The socio-economic backwardness of religious minorities projected the inter-ethnic, inter-community gap that leads to the degeneration of left politics. It seemed that the populist movement of TMC and the political iconization of Mamata Banerjee provided a sense of hope among the long-term subjugated social groups. Therefore, it benefitted the TMC in electoral victory.

The numerous welfare policies initiated by Modi, often based on earlier Congress planning, including Jan Dhan Yojana, one of the biggest financial schemes in the world, opening bank accounts for 30 crore uncovered households, and Kisan Yojana, a direct income support scheme for the farming community. Other mega programs were Awas Yojana, which provided housing to 1.5 crore poor people; Pradhan Mantri Ujjwala Yojana, which created smoke-free kitchens for 70 crore families; Swachh Bharat Abhiyan (Clean Bharat) and provided toilets to around ten crore people. The BJP criticized the Trinamool Congress for allegedly favoring Muslims. 'Nation First, national security, zero-tolerance approach to terrorism, the welfare of soldiers, battling infiltration, implementing the Citizenship (Amendment) Bill, combating left-wing extremism, Ram Mandir, Jammu & Kashmir - Article 370' were some of the key themes of Modi's populist campaign. Communalism plays a determining role in the electoral politics in Nadia district, West Bengal. Political parties and politicians use the communal division in population as the primary card during elections. As a result, the voters of the Nadia district very often vote based on religious considerations and local problems and issues.

However, the trend is changing slowly yet gradually. The sign of such consciousness is reflected in the voters' opinion regarding the most crucial issue

in the 2018 Panchayat election. However, there are visible signs that Bengal electorates are maturing, and the election is becoming more competitive. Nadia district is also no exception to that. Maybe in the coming days, communalism in politics may not remain a solid card to win regional elections. It is changing the course of electoral politics in the Nadia district. An electoral pattern indicates the ideological shift from Left to Centre and now emerging right-wing trends in the Nadia district electoral politics.

ASSESSMENT OF RURAL TOURISM DEVELOPMENT IN KALIMPONG DISTRICT, WEST BENGAL, INDIA

Amita Halder and Sanjay Kumar

Abstract

Rural Tourism is understanding and going through the rural lifestyle, nature-based activities, natural products or it could be a modified form of ecotourism. In India it is growing in a vast scale. This paper aims to provide a holistic view of rural tourism sites and the success factors for the development of rural tourism in Kalimpong district, West Bengal. Based on an empirical study with the help of secondary data sources and observation of field study. A qualitative method is used to review the current scenario of the rural tourism sites in Kalimpong District. A SWOT analysis method is also used to identify success factors working behind developed rural tourism in the study area. The study highlights, Kalimpong district as a popular rural tourism destination and recognized the strength, weaknesses, opportunities, and threats of rural tourism in the study area.

Introduction

To enhance and sustain the quality of rural life, tourism is one of the essential sector and act as contributor. Rural tourism (RT), not a new concept for World (Gao & Wu, 2017; Roslina, Dupre & Wang, 2021) but this trend has emerged from last ten years in India. Rural tourism evolved in mid 70s in developed countries (Lane, 1994; Verma and Jain, 2018; Duha, 2021), its interest raised among people in the second half of the 20th century and became a useful tool for the development of rural areas (Duha, 2021). Indeed, globalization and urbanization have had a significant impact on the international, national, and regional tourism industries, leading to increased priority and profitability in many cases (Lane, 1994; Duha, 2021). This combines rural amenities and activities to offer visitors an authentic and enriching experience in rural areas (Fleischer and Tchetchik, 2005; Gartner, 2005). According to the United Nations of World Tourism Organization (2017), this form of tourism focuses on providing tourists with a deeper connection to the countryside (remote or rural areas), local culture, and traditional ways of life and characterize on the basis of population density and settlement size,

land use and economy, and traditional social structure (Lane, 1994). This provides tourist relax from their busy schedule with pollution-free environment, fresh air, open-wide space, connecting with nature, and going back to their roots i.e. far away from the city (Irshad, 2010;). It has many subsets like agri-tourism, cultural tourism, homestay tourism, eco-tourism, etc. (Irshad, 2010; Fleischer and Tchetchik, 2005; Ashtani, 2005). According to the Ministry of Tourism of India (2022), rural tourism is working as an integrated model, because it took account of various resources like cultural, Social, economic, and environmental aspects and the role of the stakeholders (Cawley & Gillmar, 2007). Indian government had indeed been promoting rural tourism as a means of sustainable development in rural areas so that people can become self-reliant or Atma-Nirbhar. It is an effective tool to eradicate poverty, increase the quality of life of local people, development of remote areas (Roberts & Mitchell, 1998). In today's world homestay business is a perfect option for rural tourism and indeed a component of the broader tourism and hospitality industry, and it shares some key characteristics with other service-based businesses within this sector. Rural homestay is an important part; because without staying with local people, tourists cannot participate actively in rural activities. Facilities like accommodation, food, beverages, Products, and infrastructures are taken into consideration to develop rural tourism. Rural tourism gives new rise in generating employment and income, entrepreneurship, and empowering local people and women (Das, 2021). It is also preventing the out-migration of youth from rural areas. Rural tourism not only gives work opportunities but also promotes the environmental, economic, and socio-cultural sustainability of rural areas.

Study Region

Kalimpong district was selected for this research work, as its 21st district of West Bengal in 2017 carved out from the Darjeeling district. The district extents from 26°51'N and 27°12'N latitude and 88°28'E and 88°53' E longitude. The district has consisted of three community development blocks and shares boundary with Sikkim, and Bhutan. It is famous for Orchids and known as the "Land of Orchids". Kalimpong has hilly areas, natural beauty, picturesque villages, river valleys, culture, heritage, etc. It is observed in (**Table-**1) that this district comes under rural areas, bounded by forests, and diversities of flora and fauna. The main source of economy and livelihood is agriculture. There are many variations in agriculture. Cash crops (Ginger, Large Cardamom), Plantation crops (Tea, Medical plants, Cinchona, Pineapples), Horticulture (Orange), floriculture, and Orchid culture are also the attractions of this region.

Kalimpong is recognized as a natural greenhouse region (Sharma & Mandal, 2020), traditionally different from other districts of West Bengal and inhabited by ethnic groups (**Table-**1).

Table- 1: General Information on Kalimpong District to Develop Rural Tourism.

Attributes	C. D Blocks of Kalimpong District		
	Kalimpong I	Kalimpong II	Gorubathan
Total Population	74746	60663	66830
Area (Sq.km)	360.40	241.26	442.72
Density (Sq.km)	210	280	140
Number of households	15358	13172	12662
Rural Areas	Mostly rural areas except one census town Kalimpong	Consist only rural areas	Consist only rural areas
Forest area	Forest area is 52% of the total district		
Bio-diversity	This region comes under eastern Himalayas. It is rich with different types of flora and fauna i.e. Mammals - 90species, Orchids - 300 species Birds- 550 species.		
Economy	Mainly depend on agriculture. About 80% people of this district associated with farming for their livelihood.		
Agricultural Landuse under Cultivate (Percentage)	37.19	34.5	44.17
Variation of Agriculture	Subsistence farming, Cash crop raising, Plantation farming, Horticulture, Floriculture, Orchid culture, Sericulture		
Accommodation for tourist	Homestays		
Tradition	Society is traditional because of inhabited by ethnic people like Gorkha, Lepcha, Bhutia, Etc. Religions are Buddhist, Hindu, Christian, Islam		
Small scale industries	Handicrafts, Agro-based products, Homestay		

Source: District census handbook of Darjeeling (2011)

It is one of the most popular tourist destinations among other destinations of West Bengal, but comparatively is a latecomer on the tourist map. It is attractive for its landscapes, pleasant weather, and richness of biodiversity, ethnic culture, historical heritage, handicrafts, and panoramic view of Mount Kanchenjunga. In current times, tourists prefer niche types of tourism, in which locations are off-beat destinations, rather than known tourist places. This year, eight villages from Kalimpong district have been nominated for the annual "Best Tourism Villages" by UNWTO.

Objectives

The major objective of the present study is to review the current scenario of rural tourism sites and to identify key to success factors of rural tourism in Kalimpong district.

Database and Methodology

For the study, both primary and secondary data have been used. Primary data was gathered from personal observations and interactions with local people and homestay owners and online with local. Secondary data have been collected from relevant documents of published research papers, reports, and books. This dataset include- District census handbook of Darjeeling (2011), Kalimpong the Nest of smile (2018), Kalimpong Calling (2019), document on Homestays of Kalimpong (2022), and Homestays of Kalimpong (2023) published by District Magistrate of Kalimpong, West Bengal Homestay Tourism Policy (2022) published by Government of West Bengal, District survey report of Kalimpong (2022) etc. Reports and books are published by the district administration of Kalimpong. Schemes and policies-related documents published by West Bengal Government in 2022. All these are used to meet the objectives of the study. Based on the primary and secondary data, a SWOT (Strength, weakness, opportunities and threat) analysis has been done to identify key success factors for rural tourism development in the study area. SWOT analysis is a Conceptual Framework (**Fig. 1**) for identifying and analyzing an organization's strengths, weaknesses, opportunities and threats. Strength characterizes business as competitive advantage over others; Weakness characterize business as disadvantage relative to its competitors; Opportunities elements in the external environment that allows it to formulate & implement growth strategies; Threats elements in the external environment that can endanger the business and its ability to operate. The primary goal of SWOT analysis is to increase awareness of the factors that go into making a business decision or establishing a business strategy.

Result and Discussion

The current scenario of rural tourism sites in Kalimpong District

Kalimpong District is a hill station covered with reserve forests, river valleys, and foothills of the Himalayan region. Its elevation varies from 131 meters to 3163 meters (**Fig.** 2). Out of the total population in Kalimpong, 9.1% of people live in urban areas, while 90.9% of people live in rural areas (Census, 2011). People in rural areas are connected with agriculture with vast area of floriculture and agrarian resources and a few tea gardens along the southern Tarai and Dooars region of Gorubathan block (Podder, 2020). Most of the villages of three blocks of Kalimpong district are inhabited by ethnic people like Tamag and Lepcha. Based on natural and human resources, rural tourism has been growing in different villages of Kalimpong District since 2011-2012 (Sharma & Chettri, 2023, Das, 2021). Mostly tourism sites have been developing in remote villages within the forest and hilly tracts in the Kalimpong region (Das, 2021). Every three blocks of Kalimpong have rural tourism sites, from them some are very popular destinations and others are little known.

Kalimpong-II has the greatest number of rural tourism destinations because it comes under the old silk route circuit, which is connected to Sikkim. Homestays are one of the key factors to develop rural tourism in this area, which varies from 1015 meters to 3163 meters. In Kalimpong I and Gorubathan block, rural tourism sites have been developed at middle altitudes (1015 meters to 2024 meters) and nearby roads and rivers. Kalimpong I mostly come under urban areas. So, here new rural tourism sites are now developing like Chuikhim, and Nimbong. Gorubathan block comes under in Dooars region and due to accessibility hotels are grown up, that's the reason homestays are not more developed here. These rural tourism sites are also known as eco-tourism villages. These are Ramdhura, Sillary Gaon, Ecche Gaon, Rikisum, Loly gaon, Chuikhim, Kagey, Jhandi etc. These villages are picturesque, lush green trees, traditional homes, hills side cultivation, home of Orchids and different flowers, cinchona plantation, tea gardens, and majestic views of Kanchenjunga and hospitality of local people.

Strength

In the study area, under strength mainly 5 factors identified based on literature review and observations, which the potential resources are playing important role in the success of rural tourism (**Fig.** 2 and 3).

The factors are identified by using SWOT (Strength, Weakness, Opportunities, and Threats) analysis. Strength and Weakness are considered as internal factors i.e. activities involved in these factors are controllable and can be changed like location, team, intellectual properties etc. And on the other hand, Opportunities and Threat are external factors i.e. activities involved in these factors cannot be changed as under opportunities advantage can be taken but under threat only precautionary measures are taken. Ex. competitors, prices and customers (**Fig.** 3).

Historical

Natural: Natural resources are the Potential component to the development of rural tourism in the Kalimpong District (**Table-**3). The unique mountainous topography, river valleys, mesmerizing weather, majestic view of Mount Kanchenjunga, Night view of various cities from the hill region, diversities of flora and fauna, picturesquare villages and lush green trees and forest of pine and Oak, tea garden attracts a huge number of domestic and foreign tourist (Das, 2021: Bhutia, 2014: Khan and Mitra, 2017: Bhattacharya et. al, 2014). These are the key reasons for the successful development of rural tourism in Kalimpong district, Darjeeling Himalayan region.

Cultural

In rural tourism, tourist gains experiences from the local art, culture, and lifestyle of local people (Bhutia, 2014). Kalimpong is a full variation of traditional art, culture, communities, and religions. Because of the trade route to Tibet, this is earlier known as the old silk route passed through Kalimpong. In this region, various types of tribal people inhabited like the Rai, Damis, Limbus, Gurungs, Bhutia, Sanki, Sherpa, Khas, Yolmo, Magar, Newars, Tamangs, Bhujel, Kami, Lepcha, etc. The Lepchas are the original indigenous tribes in the study area. Each of these people is very unique in their culture, religion, and heritage. Most people practice Hinduism, followed by Buddhism, Christianity, and Islam. Their main languages are Nepali, Hindi, Bengali, and English. Here, Hinduism is pre-dominated, but Buddhist and Christian culture is also an attraction of this region. There are so many popular monasteries, temples, and churches (tab no. 3) in the three blocks of Kalimpong District. Kalimpong is also known for its traditional handicrafts, wood carvings, embroidered items, bags & purses with tapestry work, copperware, and Tibetan jewellry. Cuisine: In Kalimpong district, another attraction is delightful ethnic cuisine like Momo, Gundruk, Ko Jhol, Thukpa, Kinema KO Jhol, Sel Roti, Aalu Dum, and Ningroo with Churpi (One Kind of Cheese), Shya Phaley, etc.

This region is also renowned for cheese, noodles, and lollipops. Organic Vegetables and homely food of local people are preferred by tourists. It changes the taste buds of tourists and attracts tourists to rural tourism. Fair and Festivals: The people have come from different ethnic groups. There are so many fairs and festivals celebrated with great joy like Christmas, Diwali, Dusshera, and Losar. A large fair is held at Beni (the Confluence point of river Teesta and Rungeet) on the 14th of January every year. They are celebrated their fair and festivals with traditional dance and music like ghatu dance, dhan, damphu, Kaura, Maruni etc.

Historical

Kalimpong has its unique history. Firstly, Kalimpong was ruled by Sikkim still 1706 when Bhutan invaded Sikkim (Podder, 2020). Then it was acquired by the British and established colonial rule. Kalimpong is connected with Tibet, Nepal, and Bhutan by trading and sharing the national and international border. That's the reason many ethnic cultures mixed over. Donzong kingdom of Sikkim and British ruled over Kalimpong. They left their culture, Architecture (tab. no. 3) and artifacts like Tibetan style, Scottish, Roman, etc. In 1947 Kalimpong become a part of West Bengal (**Table-**2).

Accommodation

In Kalimpong region, tourism developed in the remote areas, which have natural landscapes, and pollution-free, fresh air. Rural tourism has been implemented in the various villages from three community block of Kalimpong district. The Sites are known as the off-beat destination of rural tourism for their crowded and hassle-free environment from urban areas. Rural Homestays are playing a vital role in rural tourism (Ministry of Tourism, 2023). Here, Homestays are the main accommodation and one of the attractions for tourists in rural tourism in this area. Homestay is an affordable alternative accommodation for tourists (Sharma & Chettri, 2023; Kumaran et. al, 2019). Where tourists are staying with local families, thus enabling them to gain knowledge and experience the culture, cuisine, and lifestyle of local people (Ministry of Tourism, 2023). Also, tourists are welcomed and can experience the traditional hospitality of the host family and the local community. It gives a unique and gracious feel to the tourist. In Kalimpong District, Homestays are a growing phenomenon in rural tourism in the study area (Das, 2021). In 2022,

there were 402 registered homestays in the three blocks of Kalimpong district. Now, it has increased to 1009 in 2023. It has increased significantly around 60% within one year. Mostly Homestays are concentrated in the Kalimpong II block (73%), followed by Kalimpong I block (20%) and Gorubathan block (7%). Kalimpong-II block is highest in the growth of Homestays than the other two blocks (**Fig.** 4). Because of some factors are working in this area like high altitude, conducive climate, large forest area, organic farming and silk route region, etc.

Activities

Kalimpong District has mostly hilly areas except for the South-eastern part of Gorubathan block. The people are associated with agriculture and the nature of this region. They are transforming their traditional agriculture, and nature-based knowledge into tourism activities. These activities are trekking, hiking, camping, river rafting, walk-in Jungle, identifying the plants and organic farming and harvesting, local festivals, nature photography, Mount biking and cycling, and bird watching. The Neora Valley National Park and forest are known as the "Paradise of Birds" in Kalimpong block II. The villagers in a group or individual are working as a guide. These activities keep engaging tourists with the local people.

Organic Farming

Kalimpong district has potential in organic farming and agro-horticulture for its temperate climate. According to Census (2011), more than 80% of people in Kalimpong depend on farming to manage their livelihood. The district is producing paddy, maize, millets, pulses, oilseed, and potatoes in small amounts, and medicinal plant varieties with the help of organic cultivation (Bhattacharya et. al, 2014). But it is widely known as one of the leading producers of large amounts of cardamom, flowers, and various cash crops like ginger, betel-nut, oranges, organic tea, Dalle Khursani (small chilies), and Mulberry Seri-culture (Chakraborty, 2023; Ram and Maji, 2018). The tribal people of Kalimpong like Lepcha, Bhutia, Rai, etc have utilize their family members as agriculture labour and using local resources, through traditional knowledge and methods for organic farming (Patel and Lepcha, 2023). These methods are more environments friendly (Biswas et. al., 2011). Over time period organic farming has been growing interest among tourists. It's become an opportunity for villagers and a success factor of rural tourism. Various villagers (rural tourism sites) of Kalimpong district, offers tourist to stay in farm-stay and homestay to gain knowledge of organic farming and the livelihood of local people.

Government Policies

Government policies are an important factor to develop rural regions through rural tourism. The entire stakeholders, who are related to tourism activities is bounded by local government and state government regulates. The government of West Bengal has taken many initiatives to growth of rural tourism through creating alternative income generate, employment, business opportunities, and community development. Rural homestay is an integral part of rural tourism. To promote homestay and increase local entrepreneurship, the state government gives the incentives of 1.5 lac rupees to each eligible homestay owner to achieve and maintain basic standards of homestay. Also gives subsidies on electricity and homestay businesses. No commercial taxes are levied on homestay owners, who have not more than 6 rooms (**Fig. 4**).

Homestay owners can register their homestay in the District Magistrate office and taken benefits from homestay tourism policy 2022. According to the Department of Tourism (West Bengal), tourism policy (2019) and recognition of tourism service provider policy (2021) promoted guidelines and different criteria to grant loans to tour operators, travel agents, and tourist transport operators. The policies are mainly focused on standards of infrastructure, and quality service through appropriate standardization certification and regulation. It's categorized homestay into two categories i.e. silver and gold, which are based on availability of facilities and infrastructure in homestays. The Department of Tourism associated with the Department of Agriculture of West Bengal encourages indigenous communities to adopt organic farming. Tourists can learn the practices of organic farming procedures from homestay owners and enjoy rural nature.

Opportunities

Rural tourism is focused on rural areas for sustainable rural development (Das, 2021). It has brought many opportunities in rural areas like employment, business, entrepreneurship, women empowerment, and infrastructural development (Wilson et. al, 2014). It also helps to boost self-confidence, leadership role, and various skills in local people.

Employment

In this region, rural tourism has been giving work opportunities to the local people (Bhutia, 2014). Their main economy is depending on Agriculture (Census, 2011). After agriculture, tourism is another main economic source for local people.

Rural tourism is creating an alternative income and employment opportunity for young and old people as well as women in this area. In this region, most of the people are directly and indirectly connected with the tourism industry. At present, the district has many registered and un-register homestays. The total number of registered homestays is 1009. Officially, this 1009 household is working under rural tourism. In rural homestays, women are the main worker, and other family members are also involved in the work. Most of the rural tourism destinations are not accessible by public transport, only private cars as an option. A large portion of local people associated with transportation business. From 2022 to 2023, 60% of Homestays have increased. So, it is also increased employment opportunities. In the study area, floriculture is one of the important components of the development of tourism and employment opportunities for local people (Sharma & Mondal, 2020).

Business Opportunities

Tourism gives new business opportunities in any region. In Kalimpong district, rural tourism boosts the local economy and much more in the peak season of tourism during Mid- February to June and October to Mid-December. People engaged in different types of works, because of the diversification of nature. The people are working as tour guides, car drivers, homestay owners, and cooks, and helping hand in the homestay, entrepreneurs, and handicraft makers. Some people are working as restaurant workers, sellers of local food vendors, etc (Bhutia, 2014; Das, 2021). It can be observed that employment and business opportunities have been increased in the study area.

Entrepreneurship

In rural tourism, rural homestay is an integral part. It is playing a vital role in the development of rural tourism in Kalimpong district. According to Association for Conservation & Tourism (NGO) (2023), North Bengal has a total of 3000 homestays. Kalimpong District has a one-third portion of it. It is observed, that from 2022 to 2023, entrepreneurship has increased. Male entrepreneurship increased by 44.59% and female 15.55%.

Leadership Roles

Local leadership is a success factor in rural tourism development (Wilson, 2005). Leadership should be strong, committed, and effective in destinations across all levels like governments, business persons, and communities so that these

stakeholders play a proactive role in rural tourism (Dwyer and Edwards, 2010). Destination leadership must include long-term strategic planning, that helps the destination to achieve its potential development (Haven-tang & Jones, 2012, Pp-30). Leadership encourages innovative development of the rural destination, which is creating more sustainable rural tourism with its society, economy, and environment (Mitchell and Hall, 2005; Haven-tang & Jones, 2012). In Kalimpong, rural tourism allows for increasing leadership quality for local people. It also gives support to get social, cultural, and environmental benefits to local businesses. Homestay owners, tourist guides, and small businesses like vendors, food sellers, and those connected with the rural tourism industry in Kalimpong, are gaining self-confidence, and economic independence. West Bengal Government and Various organizations are helping them through skill training to shape their life and build leadership qualities.

Infrastructure Development

Rural tourism gives a new shape of rural areas. Central Government and State Government are trying to rejuvenate the rural areas through better roads, communication, sanitation, electricity, and drinking water. Drinking water has supplying through 'Har Ghar Jol' project. National Highway 717A is under construction, which connects Kalimpong to Sikkim. It helps rural areas of Kalimpong to join the national highway grid.

Weakness

There is no doubt Kalimpong is a famous tourist destination and has potential to develop niche types of tourism. For some factors, it is lag behind in other parts of India. Kalimpong is connected mainly by roads to other districts and states. Most of the beautiful rural tourism destination is located in inaccessible areas. Village roads are in bad conditions like Ramdhura to Icche gaon, Algarah to Rishop, Lave to Kolakham, Simanadara, and a majority of Lingsey, Lingsekha, Kagey, and Gitdabling gram panchayat has no accessible road by Jeep in Kalimpong II block, Chuikhim, Yelbong part of Kalimpong I block and some parts of Gorubathan block, etc. Most of the destinations are accessible by Jeep. Its price is too high and tourists can't afford sometimes. Infrastructure is also not good enough like some destinations have no geyser option in homestay. There are some issues in water supply and communication. Mobile Network is not getting everywhere. For drinking water and domestic work, they are dependent on local Jhoras, Neora sources, Dhaula and Relli rivers, water reservoir. One of the biggest problems is that these tourist destinations are not suitable for all weather. Here tourism is a seasonal cycle i.e. Mid-February

to June and October to Mid-December. Kalimpong comes under seismic zone IV and landslip frequently occurs during monsoon season. Marketing strategies are not well maintained. There is also no option for online booking and online payment and have not any specific web portal. It cannot be reached by others states of India. Most tourists come from various districts of West Bengal, the neighboring state of Bihar Jharkhand, etc, and Bangladesh. Tourists are getting information about destinations from social media like Facebook, YouTube blogs, and family and friend circles. Hosts (local people) and guests (tourists) do have not much knowledge about rural tourism. Local people do have not proper training and skills, knowledge of rules and guidelines, and proper management of rural tourism.

Threats

Kalimpong district has a small area. Due to the improvement in tourism and floriculture, Kalimpong has witnessed urbanization (Subba, 2020). Growth of urbanization, there is a raising problem of traffic congestion. The reasons of traffic congestion are massive congestion of tourists, carrying capacity of roads and numbers of vehicles. It happened due to the pressure of the huge number of tourists at seasonal times in Kalimpong. It is noticed that the unplanned growth of homestays and tourist spots is increasing without proper planning and management. It has an impact on land cover and changing land use pattern of Kalimpong. Due to overcrowding by tourists, places are facing environmental problems like noise pollution, solid waste management, water crisis, etc. Tourists are coming from urban areas and stay with local people. It gives negative impacts on rural youth and changes their traditional lifestyle.

Conclusion

Rural tourism is a new phenomenon in Kalimpong. It reshapes rural areas and enhances the quality of life of local people as well. Kalimpong has many strengths of rural tourism. This gives many opportunities to local people i.e. employment, various business opportunities and economic independence. Here, women are actively participating in rural tourism through homestay. This leads them towards empowerment. With the help of these strengths and opportunities, weaknesses and threats should be overcome. It should be the collective effort of Government, local people as well tourists help to develop sustainable rural tourism. Local people and tourists must be aware of the rural tourism concept and its consequences. So that, through rural tourism creates a positive impact on socio, economic and environmental upliftment of the local communities in Kalimpong.

Abstract

The aim of the study is to examine the Rainfall characteristics, rainfall recharge, and water balance of the Hundri River basin. The basin is situated in a semi-arid climate with low precipitation and high evaporation rates. The primary geological formations in the basin are Granite and Gneisses, which constitute a hard rock terrain with varying degrees of permeability contingent on fracturing and weathering. Over a span of 30 years, monthly precipitation data from 19 stations have been collected, converted, and tabulated to derive seasonal and annual rainfall figures. The mean annual rainfall is distributed as follows: winter (5 mm), summer (68 mm), South-west monsoon (414 mm), North-east monsoon (130 mm), and annual (617 mm). The analysis of seasonal rainfall reveals that the basin experiences the highest precipitation during the south-west monsoon season. The total surface water resources available in the basin are estimated to be 2,189,116,000 m^3. Groundwater recharge through rainfall was estimated using eight different empirical equations proposed by Radhakrishna, U. S. Geological Survey method, Chaturvedi, U.P. Irrigation Research Institute, Bhattacharjee, Amritsar Formula, Kumar and Seethapathi, and Krishna Rao formula. The recharge percentages calculated using these empirical equations were found to be 10, 15, 20, 29, 18, 20, 14, and 8, respectively. The mean annual recharge for the basin is calculated to be 103 mm. Furthermore, the total groundwater resources are estimated to be 365,444,000 m^3, which accounts for approximately 17% of the annual rainfall.

***Key words*:** Mean rainfall, Rainfall variability, Rainfall ratio, Rainfall recharge, Water balance

Rainfall is a critical ecological parameter that has significant impacts on the ecosphere, ecological community, and economic development of any region. In India, a country with a strong agricultural sector, rainfall plays a pivotal role in shaping various aspects of agriculture, including land cover patterns, intensity of land use, farming operations, farming systems, and farm productivity levels [1]. The agricultural sector, which includes horticulture, animal husbandry, dairy, and fisheries, heavily relies on the monsoon rains, which are essential for crop growth and production. However, the distribution of rainfall across the country is irregular and unequal, leading to dry spells during the rainy season, resulting in crop failures and low yields in some areas.

Understanding the rainfall patterns, including total rainfall, daily, monthly, seasonal, and annual distribution, is vital for effective crop and water management planning. It helps in designing irrigation, drainage, erosion control, and flood control structures. Furthermore, the analysis of monthly, seasonal, and annual rainfall patterns is essential for ensuring a continuous water supply for domestic and industrial uses [2]. Therefore, it is crucial to monitor and analyze rainfall patterns to ensure sustainable agricultural practices and water management in India. Policy decisions regarding cropping patterns, sowing dates, and the provision of drinking water in both urban and rural areas are facilitated through the examination of rainfall data [3]. Furthermore, such analyses contribute to the comprehension of micro-level rainfall variability, which is of utmost importance for the planning of agriculture, land, and water resource development [4]. The evaluation of surface and subsurface water resources plays a crucial role in addressing future hydro-meteorological disasters and guaranteeing sufficient water availability for agricultural, irrigation, industrial, and domestic purposes. A normal distribution of rainfall is indispensable for the maintenance of favourable vegetation cover, the promotion of ecosystem health, the facilitation of groundwater recharge, and the assurance of robust crop production and food security.

The analysis of rainfall and studies on groundwater recharge are of utmost importance in comprehending the hydrological dynamics of the Hundri River basin, particularly within a semi-arid climate characterized by restricted water resources [5]. Through an examination of historical rainfall patterns spanning a duration of 30 years, and the subsequent classification of these patterns into distinct seasons, researchers can acquire invaluable insights into the temporal dispersion of precipitation. This enables them to identify the prevailing monsoon season (South-west monsoon) as well as the comparatively drier periods (winter and summer). Such information holds significant significance for the effective management of water resources, the formulation of agricultural

Citation: Appanna B, Raju SS, Sujatha Y. 2023. Analysis of rainfall characteristics and ground water recharge in Hundri River basin of Kurnool district, Andhra Pradesh. *Res. Jr. Agril. Sci*. 14(6): 1705-1710.

plans, and the mitigation of potential water scarcity concerns within the region.

The assessment of the overall water balance of a basin is a crucial aspect of groundwater recharge estimation through rainfall. To accurately calculate recharge percentages, researchers utilize various empirical equations proposed by experts, which consider geological characteristics, soil type, and vegetation cover. This analysis aids in determining the replenishment rate of groundwater aquifers, which are vital for sustaining domestic water supply, supporting agricultural activities, and preserving the ecological balance of the region.

MATERIALS AND METHODS

Study area

The Hundri River, a tributary of the Tungabhadra River, originates in the fields of Maddikera in Maddikera Mandal (Fig 1). It receives a stream from Erramalas at Laddagiri in Kodumur Mandal and eventually joins the Tungabhadra River at Kurnool town. The river covers parts of 13 Survey of India Topsheets on a scale of 1:50,000. It drains a significant portion of the Maddikera, Pattikonda, Deverakonda, Gonegandla, Kodumur, and Kallur Mandals. The river falls within the survey of India (SOI) top sheet numbers 57E/6 to 57E/16 and 57I/1 to 57I/3. The river basin is in the southwestern part of the Kurnool district, lying between Northern latitude 140 35' 35" N-160 09' 36" N and longitude 750 58' 42" E to 780 56' 06" E. It covers an area of 3548 square kilometers and spreads across parts of 20 mandals, encompassing 205 revenue villages.

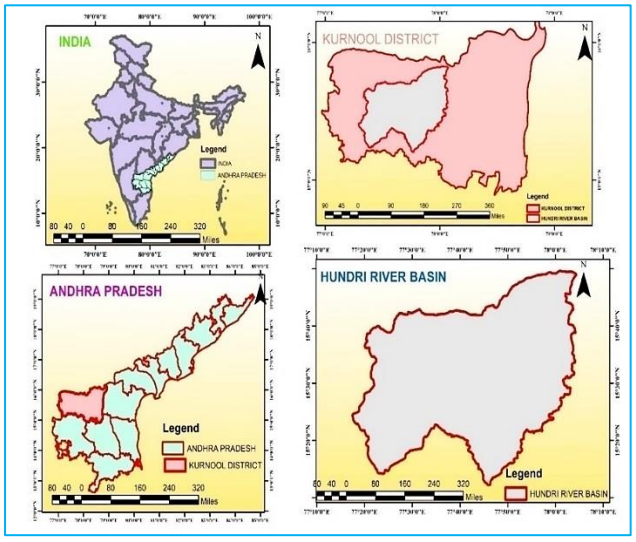

Fig 1 Location map of the study area

The investigation of the surface water resources within the Hundri River basin was conducted through an examination of the precipitation data obtained from 19 rain gauge stations. The monthly precipitation data spanning a duration of 30 years was procured from the Chief Planning Office of Kurnool district for these stations. To assess the precipitation data in terms of seasonal and annual patterns, the statistical methodologies outlined by Bhargava (1977) were employed. The average monthly precipitation, variability in precipitation, and precipitation ratio for each of the 19 stations were computed and organized in tabular form.

1). Mean rainfall = $\frac{\sum X}{N}$, Where X= variates and N = No. of. Varieties

2). Rainfall Variability = $\frac{SD}{AM} \times 100$, Where S.D =Standard deviation, AM =Arithmetic mean

3). Rain fall Ratio = $\frac{P_x P_n}{P_m} \times 100$,Where P_X = Maximum rainfall, P_N =Minimum rainfall

P_M and P_M =Average rainfall

In order to estimate groundwater recharge, a range of empirical methods proposed by Radhakrishna *et al*. [6], the U. S. Geological Survey method (1962), Chaturvedhi (1936), the Amritsar formula (1973), the U.P. Irrigation Research Institute Formula (1954), Krishna Rao (1970), Bhattacharjee (1954), and Kumar and Seethapathi (2002) were employed. The groundwater recharge was determined using each of these methods. Through the implementation of this comprehensive study, valuable insights into the surface water resources and groundwater recharge within the Handri River basin were acquired. These findings will contribute to enhanced water resource management, planning, and decision-making, thereby facilitating the sustainable utilization of water in the region.

Estimation of ground water recharge by using empirical formulas

4) Radhakrishna *et al*. (1974): 10% of the Annual Rainfall

5). U.S. Geological Survey method (1962): 15 % of the annual Rainfall

6). Chaturvedi formula (1936): R_g= 2(P-15) ^0.4

Where Rg is net Recharge and P is annual rainfall, both are measured in Inches

7). Amritsar Formula (1973): Rg= 2.5(P-16) ^0.5

Where R_g is net Recharge and P is annual rainfall, both are measured in Inches

8). U.P.I.R.I. Formula (1954): R_g= 1.35(P-14) ^0.5

Where R_g is net Recharge and P is annual rainfall, both are measured in Inches

9). Bhattacharjee Formula (1954): Rg =3.47(P-38) ^0.4

Where Rg is net Recharge and P is annual rainfall, both are measured in cm

10). Kumar and Seethapathi Formula (2002): Rg =0.63(P-15.28) ^0.76

Where R_g is net Recharge and P is annual rainfall, both are measured in inches

11). Krishna Rao Formula (1970): Rr = K (P-X)

Where R_r and P are measured in mm.

R_r =0.20(P-400) Where annual rainfall between 400- 600 mm

R_r =0.25(P-400) Where annual rainfall between 600- 1000 mm

R_r =0.35(P-600) Where annual rainfall greater than 2000 mm

RESULTS AND DISCUSSION

Seasonal analysis of rainfall of the handri river basin

Winter season

During the winter season, which comprises the months of January and February, the mean rainfall in the study area varies from a minimum of 3 mm at the Krishnagiri station to a maximum of 10 mm at the Asparistation (Table 1). The average rainfall for the entire basin is recorded as 5 mm (Table 1) indicating dry and arid conditions during this period. The Rainfall Variability analysis reveals fluctuations ranging from 155% at the Gudur station to 297% at the Kallur station with an average variability of 220 %. It suggesting significant Fluctuations in the amount of rainfall received during this period. Furthermore, the Rainfall Ratio, a measure of rainfall distribution, shows diverse patterns across the study area. It ranges from 521% at the Gudur station to 1561% at the Yemmiganur station, with average of rainfall ratio of 943%, it signifying substantial variations relative to the mean rainfall, which can have implications for water availability and agricultural planning [7-9].

Summer season

The summer season consists of March, April, and May Months. The values range from a minimum of 60 mm (Tuggali) to a maximum of 76 mm (Pattikonda) (Table 2). The overall average mean rainfall for all stations is approximately 68.5 mm (Table 2). which can be considered a relatively dry period Rainfall variability is a measure of how much the actual rainfall deviates from the mean rainfall. Higher variability indicates more significant fluctuations in rainfall amounts. The values range from a minimum of 47% (Alur) to a maximum of 87% (Bethamcherla). The overall average rainfall variability for all station is around 65.2%, indicating fluctuations in the amount of rainfall received this period. The Rainfall Ratio values ranges from minimum of 184% (Alur) to a maximum of 387% (Bethamcherla). The overall average rainfall ratio for all stations is approximately 264% reflecting considerable variations relative to the mean, which can have implications for water availability and agriculture [10-11].

South west monsoon

During the South West Monsoon season, which includes the months of June, July, August, and September, the mean rainfall in the basin varies between 318 mm at Maddikera station and 496 mm at Kurnool station (Table 3). The normal rainfall for the basin during this period is 414 mm (Table 3), Indicating the wettest season in the basin. The rainfall variability ranges from a minimum of 26% in Adoni to a maximum of 50% in Dhone station, with an average variability of 40% for the basin, indicating relatively stable and predictable rainfall patterns during this season. The rainfall ratio, of the basin varies from 110% at Adoni station to 257% at Dhone station, with an average rainfall ratio of 179% for the basin, indicating a relatively balanced distribution of rainfall compared to the mean, which can be favourable for agricultural activates [12].

Table 3 Mean rainfall, rainfall variability and rain fall ratio of the Hadri River basin (South west monsoon)

Station	Mean rainfall in mm	Rainfall variability in %	Rainfall ratio in %

North east monsoon

During the North East Monsoon season, which covers the months of October, November, and December, the mean rainfall in the basin varies from a minimum of 113 mm at Kodumur station to a maximum of 151 mm at Bethamcherla (Table 4). The average rainfall for the entire basin during this period is 130 mm (Table 4), Making it moderately wet season. Rainfall Variability across the study area shows diversity, ranging from a minimum of 56% at Peapully station to a maximum of 89% at Yemmiganur station, with an average variability of 70%, suggesting fluctuations in rainfall amount during this period. The rainfall ratio in the basin has a wide range, with a minimum of 208% at Veldurthi station to a maximum of 410% at Gonegandla station. The normal rainfall ratio is recorded as 281%, Indicating significant variations relative to the mean, which may impact water resources and local ecosystem.

The basin experiences diverse rainfall patterns across the four seasons, with varying mean rainfall, rainfall variability, and rainfall ratio. Understanding these seasonal characteristics is crucial for water resource management, agricultural planning, and climate adaptation strategies in the region [13-15].

Annual rainfall

The annual rainfall in the basin shows significant variation, ranging from a minimum of 515 mm at Maddikera station to a maximum of 702 mm at Kurnool station (Table 5). The average annual rainfall for the entire basin is calculated to be 702 mm. Regarding rainfall variability, it varies across the stations, with Adoni station experiencing the lowest variability at 25%, and Dhone station witnessing the highest variability at 39%. On average, the rainfall variability for the basin is around 33 %. The rainfall ratio also displays diversity, ranging from 103% at Krishnagiri station to 186% at Yemmiganur station. The normal rainfall ratio is recorded as 140% [16].

Table 5 Mean rainfall, rainfall variability and rain fall ratio of the Handri River basin (Annual)

The basin experiences varying amounts of annual rainfall, with some stations receiving higher rainfall (e.g., Kurnool) and others have relatively lower rainfall (e.g., Maddikera). The variability in rainfall amounts differs across the basin, with some stations showing more stable patterns (e.g., Adoni), while others exhibit higher fluctuations (e.g., Dhone). The Rainfall Ratio provides insight into how the mean rainfall relates to the rainfall variability at each station, indicating variations in the basin's overall rainfall patterns.

The Total Surface Water resources the Handri River basin: Total Geographical area of the basin × Mean annual rain fall 3548 Km^2 × 617 mm = 218, 911, 6000 m^3.

Ground water recharge

Radha Krishna method (1974)

The Radhakrishna approach (1974) proposes that the basin's aquifer recharge is equivalent to 10% of the total annual precipitation. The recharge rates fluctuate, with the lowest value being 51 mm at Maddikera station and the highest being 70 mm at Kurnool station (Table 6). The mean yearly groundwater recharge for the entire basin is estimated to be 62 mm.

U.S. Geological method (1962)

According to this According to the methodology proposed by the U.S. Geological Survey in 1962, the groundwater replenishment in the studied area, basin, or watershed corresponds to 15% of the total annual precipitation. According to this method, the recharge figures vary, with a minimum of 77 mm observed at Maddikera and a maximum of 105 mm recorded at Kurnool station (Table 6). On average, the annual replenishment of groundwater for the entire study area is assessed to be 93 mm.

Chaturvedi formula (1936)

Chaturvedi's formula (1936) derives the groundwater replenishment using the expression Rg = 2(P-15) ^0.4, with Rg and P expressed in inches. According to this method, the recharge amounts fluctuate, ranging from a minimum of 99 mm at Maddikera to a maximum of 140 mm in Kurnool District (Table 6). The average yearly recharge for the basin is determined to be 123 mm, constituting 20% of the overall annual precipitation.

Amritsar formula (1973)

Amritsar's method (1936) proposes the calculation of groundwater recharge using the formula Rg = 2.5(P-16) ^0.5, with Rg and P measured in inches. According to this approach, the recharge values exhibit variability, ranging from a minimum of 131 mm at Maddikera to a maximum of 217 mm in Kurnool District (Table 6). On average, the basin experiences an annual recharge of 182 mm, which constitutes 29% of the total annual rainfall.

U.P.I.R.I. formula (1954)

U.P.I.R.I has developed a method for estimating groundwater recharge using the formula Rg = 1.35(P-14) ^0.5, where Rg and P are measured in inches. According to this approach, the recharge values exhibit variation, ranging from a minimum of 86 mm at Maddikera to a maximum of 127 mm in Kurnool District (Table 6). On average, the basin experiences an annual recharge of 110 mm, which corresponds to 18% of the total annual rainfall.

Bhattacharjee formula (1954)

Bhattacharjee's approach has derived a means to estimate groundwater replenishment utilizing the equation Rg = 3.47(P-38) ^0.4, where Rg and P are expressed in centimeters. According to this method, the recharge quantities exhibit variability, spanning from a minimum of 98 mm at Maddikera to a maximum of 139 mm in Kurnool District (Table 6). The mean yearly recharge for the basin is determined to be 123 mm, corresponding to 20% of the entire annual precipitation.

Kumar and Seethapathi (2002)

Kumar and Seethapathi have formulated a method to calculate groundwater recharge using the equation Rg = 0.63(P-15.28) ^0.76, where Rg and P are measured in inches. According to this approach, the recharge values show variation, ranging from a minimum of 54 mm at Maddikera to a maximum of 108 mm in Kurnool District (Table 6). On average, the basin experiences an annual recharge of 123 mm, which constitutes 20% of the total annual rainfall.

Krishna Rao formula (1970)

In1970, Krishna Rao introduced an empirical relationship for approximating ground water replenishment, given by Rr = K(P-X), where Rr and P are measured in millimeters. According to Krishna Rao method.

For Regions with annual rainfall ranging from 400 to 600 mm, the recharge can be approximated using Rr =0.20(P-400)

For Regions with annual rainfall ranging from 400 to 600 mm, the recharge can be approximated using Rr =0.25(P-400)

For Regions with annual rainfall Exceeding 2000 mm, the recharge can be approximated using from 400 to 600 mm, Rr =0.35(P-600)

Based on this approach, the recharge values range from a minimum of 23 mm at Maddikera station to a maximum of 75 mm at Kurnool station (Table 6). On average, the basin experiences an annual recharge of 51 mm, which represents 8 % of the total annual rainfall.

Table 6 Average annual recharge of the Handri River basin

Yemmiganur	652	65.18	97.77	130.91	197.37	117.09	130.02	94.73	62.94	112.00	17.18

The average annual recharge of the basin has been calculated by taking the average of eight different methods, resulting in a range of values from 78 mm to 123 mm. The overall average recharge for the entire basin is 103 mm. This average recharge accounts for 17% of the annual rainfall in the region. The recharge values vary across different stations in the basin. Maddikera and Krishnagiri stations have the lowest recharge values, being less than 90 mm. Apari, Devanakonda, Dhone, Tuggali, and Veldurthi stations experience recharge between 90 mm and 100 mm. On the other hand, Adoni, Alur, Bethamcherla, Orvakal, Pattikonda, Peapully, and Yemmiganur stations have the highest recharge values exceeding 100 mm.The total Ground water Potential of the basin is worked out by ground water recharge method.

Total water resources recharge to ground water = Geographical area of the basin × Average annual recharge
3548 Km^2 × 103 mm = 365,444,000 m^3

The total Ground water resources accounts to 16.7% of the total surface water resources.

Water balance of the Handri River basin

1). The total surface water resources = Geographical area of the basin × Average annual rain fall 3548 Km^2 × 617 m = 2189116000 m^3.

2). Total water resources Recharge to Ground water=Geographical area of the Basin × Average AnnualRecharge 3548 Km^2 × 103 m =365444000 m^3. (16.7%)

3). Total Water resources stored in Reservoirs, Ponds, lakes etc = 2189711600 m^3 (10%).

4). Total water resources lost in the form of run-off = 437823200 m^3. (20 %)

5). Water lost in the form of Evaporation and Evapotranspiration 2189116000 – 1022178800 = 1166937200 (53.3%)

From the above analysis it is found that out of 218911600 m^3 of water available 10% is stored in the ponds and tanks and reservoirs if the basin, 16.7% recharge to ground water, 20 %is lost in the form of run-off and 53.3% is lost in the form of evaporation and evapo-transpiration. The surface water loss in the form of run-off could be saved and stored efficiently by constructing check dams and percolation ponds in the basin [17-18].

CONCLUSION

In summary, the research reveals distinct seasonal rainfall patterns with significant fluctuations in the study area. Winter and summer experience dry conditions, impacting water resources and agriculture. The South West Monsoon brings the

wettest period with stable rainfall patterns, while the North East Monsoon is moderately wet with variable rainfall. The annual rainfall shows notable variation, affecting water availability and agricultural planning. The study analyzed multiple methods to estimate groundwater recharge, showing diverse values across different stations. The overall average annual recharge for the basin was 103 mm, accounting for 17% of the total annual rainfall. Understanding these variations is essential for effective water resource management and sustainable agricultural planning.

Editor's Desk

June 21, 2023

The Indian Journal of Spatial Science is a publication of the 'Indian Society of Spatial Scientists". The aim of the 'Indian Society of Spatial Scientists' (ISSS) is to make 'Research in Spatial Science' of global standard with worldwide reference. It is concerned with all fields of Geography, Geology, Geoinformatics, Social Science and other Spatial Sciences as well. Basically, it is intended for the publication of research by the young scholars of Geography and allied disciplines all over the world. Currently, it is a Quarterly Journal published as Spring Issue (on the eve of Vernal Equinox: March 21), Summer Issue (on the eve of Summer Solstice: June 21), Autumn Issue (on the eve of Autumnal or Fall Equinox: September 23), and Winter Issue (on the eve of Winter Solstice: December 21).

The IJSS is a UGC approved (formerly, and yet to be Care-listed), peer-reviewed/ refereed open access journal with all the content published under free licenses, and anyone is allowed to read, download, copy and distribute them. Tremendous research has been going on in the fields of applied geography, geoinformatics, earth science and social sciences at the college and university level all over the globe and in the near future, the Indian Journal of Spatial Science is expected to be a gateway for some of the best research articles and presentations. Excepting the 'honourary members' and 'authors of high repute', it is a 'subscribing' journal and there is no processing or other charges for publication of Articles.

The secured website (https://www.indiansss.org) has been completely redesigned in which all past issues are available and can be accessed free. One can register free and log in to explore easily. Manuscript can be submitted online. Before review, all articles are checked for plagiarised content using 'Turnitin'. After review, the Copy Editor edits the English language as and where necessary. The journal carries the same ISSN 2249 3921 (for the Print / DVD Version) and ISSN 2249 4316 (for the On-line Version).

Contributions to the IJSS by the young researchers are always welcome. However, they should strictly conform to the Instructions for the Authors. The content of this journal does not necessarily represent the views or policies of the ISSS except where explicitly identified as such. Hence, the editor or the ISSS shall in no way be responsible for the views expressed by the authors in their articles.

Finally, a blanket 'thank you' for all the contributors who chose our journal based on its quality and urge them to keep contributing and spread the news among institutions, researchers, professors and fellow colleagues. I do convey my heartiest congratulations to our Hon'ble Peer Reviewers, Copy Editors, Composer and the Website Manager for their sincerest efforts without which this issue could not be published on time.

I do hope this endeavor by the Indian Society of Spatial Scientists will continue to keep its tradition, style and objectives.

This particular issue is a tribute to our Late President, Prof. Avijit Gupta. An obituary has been added to make our readers, members and others informed about his contribution in the field of fluvial geomorphology, geomorphology of humid tropics, environmental management, and application of remote sensing in the study of geomorphology and environmental management.

Abstract

Water is precious in the areas like drought-prone due to inadequate rainfall and surface water. The available drinking water sources are prone to pollution and contamination and content of high percentage of fluoride etc. In a region like Rayalaseema of Andhra Pradesh, which is prone to drought and identified as one of the country's driest regions. In these circumstances, potable water is essential to assess the water quality for Drinking. Groundwater is the rural population's main drinking source in the proposed study area. Therefore assessment of water quality is essential and has far the most important. The present paper is intended to assess the water quality in the Tungabhadra River Basin of Kurnool district to determine the suitability of available Groundwater for drinking purposes. In this connection, the water quality index(WQI) has been applied to determine the different physico-chemical parameters of the Groundwater at various locations in both pre and post-monsoon seasons for 2021. The distribution of water quality parameters across the basin is evaluated by the IDW interpolation method in GIS. The water quality index was calculated from the observed parameters indicating both pre-monsoon (79.68) and post-monsoon (86.82) seasons as poor water quality.

Introduction

Water safety and security is an emerging issue worldwide which has compound effects on various sectors of the economy. The basin area lies in the semiarid region of Rayalaseema region. The basin faced a severe crisis in managing water resources to meet all requirements, viz., drinking, households use, irrigation and industrial development. In general, surface water is scant in the semiarid regions owing to the inconsistency of monsoon rainfall and high rate of evaporation. Hence, people in such areas must depend more on groundwater resources for life support. The Tungabhadra and its tributary Hundri in Kurnool district are the major sources for increasing groundwater potential. Groundwater makes up most of the drinking water source of the basin area.

Over the years, groundwater has been contaminated, and the quality of the basin area has deteriorated. A common source of contamination of groundwater in the basin area is open defecation, inadequate sanitation facilities, especially in rural areas. Discharge of untreated sewage (Reddy, 2014, Prabavathi, 2015), municipal sewage, chemicals and waste materials (Rajeswari, 2009), construction material and cement manufacturing activities (Tharani, 2021), runoff and seepage of residues of chemical fertilizers and pesticides (Rayudu, 2020) industrial effluents and various malpractices related to waste disposals. The contamination of groundwater can have adverse effects on human health. There is a prime necessity to control water contamination and deterioration substances in the ecology and ecosystem of the Tungabhadra river basin.

Water quality Assessment is an important measure to the health of a basin to make necessary management and decision to control current and future pollution of receiving water bodies. Water quality is inherently linked with public health, food security, livelihoods and preservation of ecosystem and ecology, and socioeconomic growth of our societies (UNESCO, 2015). It is very much needed for policymakers, administrators, and water

quality management; if the quality has deteriorated, remedial measures are to restore it. To assess water quality, the values obtained were compared with standards prescribed by the Bureau of Indian standards (BIS) and the Indian council for medical research (ICMR).

The water quality index (WQI) Is a mathematical instrument which provides a single number that expresses overall quality at certain locations and times based on several water quality parameters (Hulye (2009), Pathak et al., 2015). Therefore, the study's objective was to calculate the water quality index of the Thungabhadra river basin to assess its suitability for Drinking. A similar type of study has been done in India by Chatterjee et al. (2007), Miraj et al. (2017), Jagadeeswari (2012), and Das Guptha (2001).

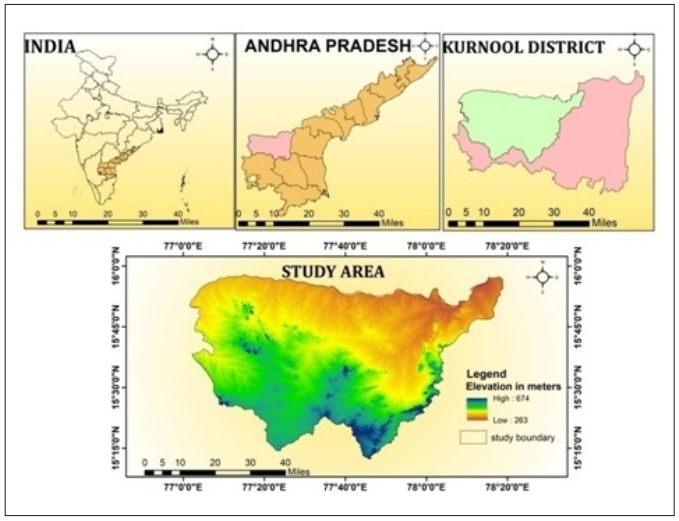

Fig.1: Location Map of the Study Area

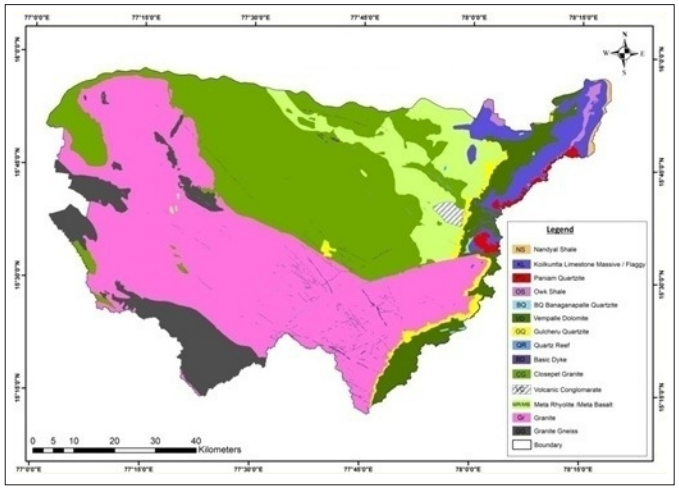

Fig.2: Geological Map of the Study Area

The Study Area

The study area of the Tungabhadra River basin is situated in the northwestern part of the Kurnool district in the state of Andhra Pradesh (India) and occupies an area of 6,993.95 sq. km. It is the southwestern district of Andhra Pradesh, and is one of the country's frequently drought-affected districts, Mainly in the western part of the district, with an average annual rainfall of about 670 mm. The main occupation and source of livelihood for this basin is agriculture. More than 70 % of the people in the basin are engaged in farming. It is predominantly an area of rain-fed agriculture. The climate of Kurnool is tropical, with temperatures ranging from 26^0 c to 46^0 c in the summer and 12^0 c to 31^0 c in the winter. Due to continuous drought, Agriculture is not the main source of income for the last decade. It lies Between North Latitude 15^0 15'00" to 16^0 0'00" and East longitude 77^0 0'00" to 78^0 15'00". It is falling in the survey of India (SOI) Toposheet No 57E/ 1 to 57E/16 and 57I/1 to 57 I/5. Geologically the basin is underlined by the crystalline rock of the peninsular gneissic complex(PGC), comprising the granitic gneisses, and granites in the west and southern part of the basin. The K-rich granite (equivalent to close pet granite) of the lower Proterozoic age, distributed in the northern part of the basin. Conglomerates, quartzite, shale, limestone, and dolomite were found as small patches in the northeastern part of the basin. The basic dykes and quartz veins are noticed in the west and southern part of the basin.

Objectives of the Study

1) To evaluate the groundwater quality in the Tungabadra river basin for drinking purposes by using the water quality index.
2) To explore physico-chemical parameters of groundwater at different locations in the study area.

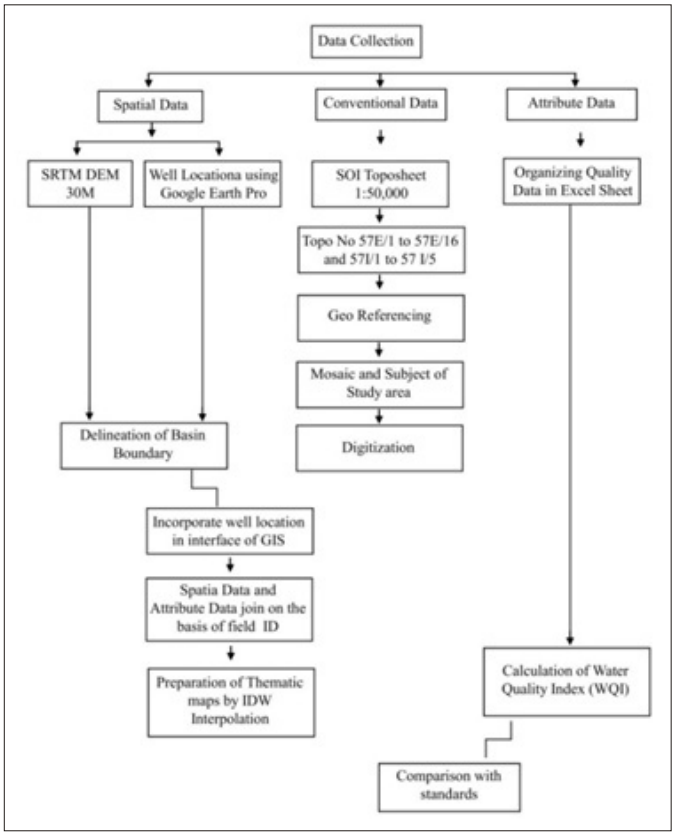

Fig.3: Methodology adopted in the present study

Methodology

The Methodology adopted for the current study is shown in Fig 2. To delineate Basin Boundary, we have used SRTM DEM 30 M Resolution, downloaded from https://earthexplorer.usgs.gov/ and Survey of India (SOI) Topographic maps of 1972 with No 57E/ 1 to 57E/16 and 57I/1 to 57I/5on the Scale 1:50000 were collected from https://www.surveyofindia.gov.in/. Downloaded SRTM DEM data were processed by using the Hydrology tool, and

topographical maps were rectified/referenced and mosaic with the help of Arc GIS 10.3 Software and the extracted basin assigning Universal Transverse Mercator (UTM), world Geodetic system (WGS from 1984) and 44 N zone projection system. The well locations at which quality data are collected from the District Water board are from Google Earth Pro. The well locations in terms of Latitudes and longitudes are written down in a notepad and then converted to a point shape file in GIS Interface. Attribute data corresponding to water quality parameters for the pre-monsoon and post-monsoon of 2021 is properly organized and organized in an Excel sheet. Spatial and attribute data are joined together based on field I.D. using the join and relate tool in Arc GIS. The Water Quality index for the current study is based on eight parameters. The calculation of the WQI was done using the Weighted Arithmetic water quality index, originally proposed by Horton (1965) and Developed by Brown et al. (1972). The first step in the calculation is to rate the quality of each parameter. Let q_n be the quality rating of each parameter where n is the no. of each parameter. It is given by Eq.1

$$q_n = 100 (V_n - V_o) / (S_n - V_o) \ldots\ldots\ldots (1)$$

Where
Q_n =Quality rating for the nth water quality parameter, V_n= Estimated value of the n^{th} parameter at the given sampling station, V_o= Ideal value of n^{th} parameter in pure water, S_n = Standard permissible weight of the nth parameter.

Computation of Quality Rating for pH

For pH, the ideal value is 7.0 (for natural water), and the permissible value is 8.5

Therefore, the quality rating for pH is calculated with the help of the following equation:

$$q_n = 100 (V_{pH} - 7.0) / (8.5 - 7.0) \ldots\ldots (2)$$

Where, V_{pH} = observed value of pH

Each parameter is given a unit weight for water quality index calculation by the Bureau of Indian Standards (BIS) And the Indian Council for Medical Research (ICMR). The standard permissible values according to IS 10500 and unit weights for each parameter are given in table 1.

Computation of Unit Weight

Unit weight has been calculated by a value inversely proportional to the recommended standard values Sn of the corresponding parameters.

$$W_n = k/S_n \ldots\ldots\ldots\ldots\ldots\ldots (3)$$

Where, Wn = Unit weight of the nth parameter, Sn = Standard value of the nth parameter, K = Constant for proportionality

The overall quality index (WQI) has been calculated by linearly aggregating the quality rating with the unit weight.

$$WQI = \sum Wn*q_n / \sum Wn \ldots\ldots\ldots\ldots (4)$$

Where, WQI = water quality index, W_n = unit weight of the n^{th} parameters q_n =quality rating of the n^{th} parameter.

Results and Discussion

To assess the water quality for drinking purposes, concentration of physico-chemical parameters presents 62 samples have been analyzed for pre and post-monsoon seasons in 2021. The seasonal analysis helps to assess the changes in the concentration of minerals during dry and wet periods due to the fluctuations in the groundwater table, amount of runoff water, duration of contact period with rock strata of the aquifer etc.

Table-3 and Table-4 provide all information about the physico-chemical parameters of the samples. Table-5 shows the descriptive statistics (maximum, minimum, and average) of the physic-chemical parameters of the groundwater samples.

The distribution of water quality parameters across the basin has been mapped by the IDW interpolation for each parameter class. Fig.3 and 4 show the spatial pattern of pH, TDS, SO_4^{2-}, No_3^-, Cl^- ,Ca^{2+},Mg^{2+} and TH in the pre-monsoon period and Fig.5 and 6 show the spatial pattern of pH, TDS, So_4^{2-}, No_3^-, Cl^-, Ca^{2+}, Mg^{2+} and TH in the post- monsoon season.

a. pH

pH is one of the significant parameters of water and decides the Acidic and basic form of water. According to BIS and ICMR, the pH of Good Quality of Water ranges from 6.5-8.5. In the pre-monsoon season, the pH of the study area groundwater sample ranges from 7.1(min) to 8.5 (max) with a mean value of 7.9, and in the post-monsoon, the importance of p^H varies from 7.2 (min) to 8.5(max) with a mean value of 8 respectively. The pH variation shown in Fig. 3-A and 5-A depicts that all the groundwater samples in the pre and post-monsoon seasons were within the permissible limits.

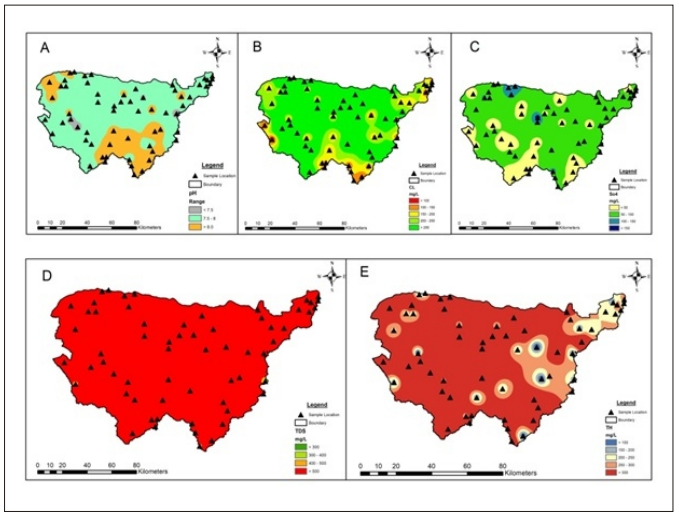

Fig.4: The spatial distribution of pH, Cl^-, So_4^{2-}TDS, and T.H. during the pre-monsoon period

b. Total Dissolved Solids(TDS)

The total dissolved solids in the basin vary from 291.84 mg/l to a maximum of 3962 mg/l with a mean value of 1246.11. The post-monsoon season TDS value ranges from 231.04mg/l to 6304 mg/l with a mean value of 1338.62 mg/l (Table - 5).out of 62 samples, 8 per cent of samples in premonsoon season and in post-monsoon season, 13 per cent of samples were found to have TDS values below the acceptable limits (Fig. 3-D, and Fig. 5-D). In contrast, the rest of the samples had higher values of TDS.

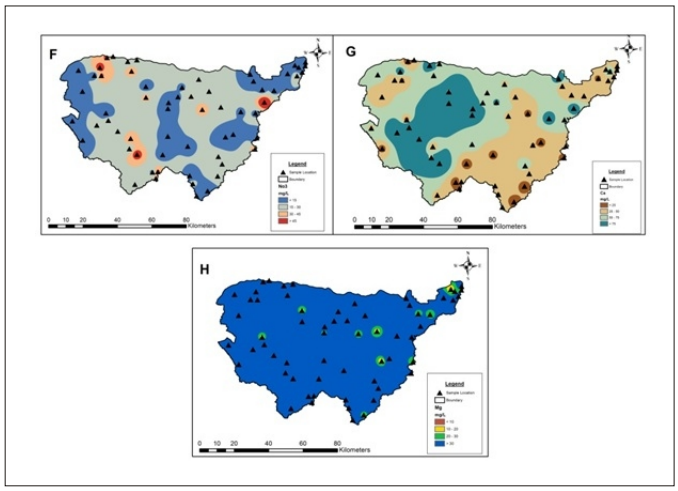

Fig.5: The spatial distribution of No_3^-, Ca^{2+}, and Mg^{2+} during the pre-monsoon period

c. Sulphates

The sulphate distribution in groundwater samples of the basin ranged from 4 to 199 mg/l. The mean value of 65 mg/l indicates that most of the wells in the study area are within the acceptable limit (Table - 5). Percentage-wise, 95 % of the sample in the pre-monsoon season had So_4^{2-} within the acceptable limits (Fig 3-C). In the post-monsoon season, So_4^{2-} ranged from 10 to 210 mg/l with a mean value of 103 mg/l (Table 5). From Fig (5-C) can be said that 72% of the area has sulphate content within the permissible limits.

d. Nitrates

In this present study area, No_3^- ranged from 1 to 83 mg/l, for which the mean value of 19 mg/l during the pre-monsoon season and in post-monsoon season No_3^- varied from 1.5 to 87.3 mg/l with the mean value of 31.16 mg/l respectively(Table-5). The spatial distribution maps(Fig. 4-F and Fig. 6-F) show that 90% of samples in pre-monsoon season and 85 % in post-monsoon season No_3^- were within the acceptable limits per BIS Standards.

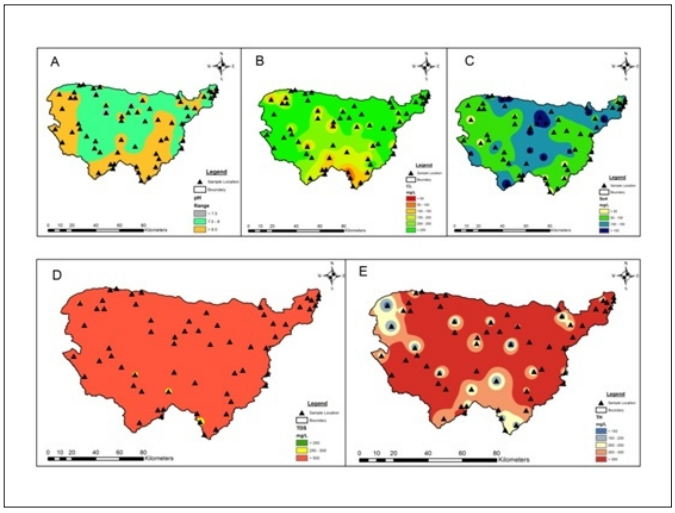

Fig.6:The spatial distribution of pH, Cl^-, So_4^{2-}TDS, and T.H. during the post-monsoon period

e. Chlorides

The chloride in the groundwater samples in the basin varies from 54 to 850 mg/l during the premonsoon season, with a mean value of 273 mg/l (Table-5). Fig 3-B shows that 56% of the area chloride concentration samples were within the permissible limits. For the post-monsoon season, Cl^- concentration ranged from 40 to 930 mg/l, with the mean value at 275 mg/l (Table-5). Fig 5-B shows that 66% of the area has chloride concentration within the permissible limits.

f. Calcium

In the current study area, the Concentration of Ca^{2+} in groundwater samples varied from 8 to 248 mg/l with a mean value of 56 mg/l, whereas, in the post-monsoon Concentration of Ca^{2+} groundwater samples, it ranged from 16 mg/l to 192 mg/l with a mean value of 57 mg/l respectively (Table-5). Figures 4-G & 6-G show that 77 % of groundwater samples in pre-monsoon season and 75 % of post-monsoon samples have Ca^{2+} content within permissible limits per the BIS and ICMR standards.

g. Magnesium

Mg^{2+} Concentration ranged between a minimum of 5 mg/l to a maximum of 97 mg/l during the pre-monsoon period resulting in a mean value of 51 mg/l (Table 5). From Fig 4-H, 21 % of the groundwater samples were found within the permissible limits in pre-monsoon. The remaining samples (79%) have more concentration than the allowable limits. For the post- Monsoon period, Mg^{2+} Concentration varies from 10 to 146 mg/l with a mean value of 50 mg/l. Fig 6-H represents that 37 % of the groundwater samples were within permissible limits. At the same time, the rest of the samples had higher values than BIS standards.

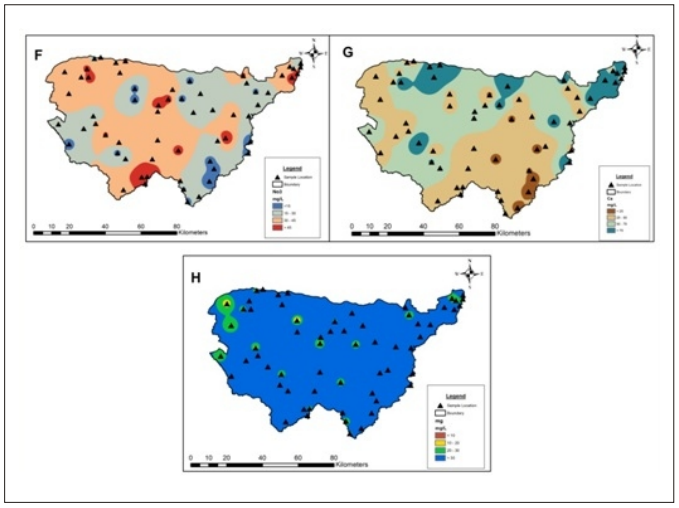

Fig.7: The spatial distribution of No_3^-, Ca^{2+}, and Mg^{2+} during the post-monsoon period

h. Total Hardness(TH)

As per the BIS and ICMR standards, acceptable limits of T.H. in natural water are usually less than 300 mg/l, while water with more than 300 mg/l is unsuitable for Drinking. In premonsoon, the Total Hardness of the Groundwater sample in this basin ranged from 82 mg/l to 978 mg/l with a mean value of 348 mg/l and in post-monsoon season, T.H. varied from 102 mg/l to 899 mg/l with a mean value of 350 mg /l respectively (Table -5). Fig 3-E represents 51 % of samples in the premonsoon season, and Fig 5-E represents 54 % of groundwater samples in the post-monsoon season within the permissible limits.

Water Quality Index

A Water quality index (WQI) summarises a large amount of data into simple terms (excellent, good, poor, very poor, unfit for drinking, irrigation etc.) For reporting to policymakers, administrators, and users consistently. The groundwater quality of the present study area, the Tungabhadra River basin of Kurnool district, Andhra Pradesh, is calculated using different physico chemical parameters such as pH, total dissolved solids, sulphates, nitrate, chlorides, calcium, magnesium and total hardness. The data collected regarding physico-chemical parameters is during pre-monsoon and post-monsoons of 2021.

The physico-chemical properties of groundwater of the Tungabhadra River Basin have been computed for pre-monsoon, and post-monsoon period (Table - 6 and Table - 7). It is followed by the computation of the water quality index (WQI), as follows:

$$WQI = \sum w_n * q_n / \sum w_n$$
$$= 86.82$$

Pre and post-monsoon water quality index values are compared with Chatterjee and Raziuddin, 2002 (Table - 2). we conclude that the water of the Tungabhadra river basin is of very poor quality for drinking purposes and must therefore be treated before use to avoid water-related diseases.

Conclusion

The results obtained from Physico chemical parameters were analyzed to calculate the water quality index during the pre and post-monsoon period (2021). The water quality index values of the Tungabadra river basin can be concluded that water is not fit for drinking purposes. Therefore, an urgent effort should be taken to monitor. Indigenous technologies should be adopted to make them suitable for drinking after treatment (filtration, disinfection etc.) by using remote sensing and GIS technologies to identify and mapping of potential groundwater zones and construction of rainwater harvesting structures such as percolation tanks, recharge pits etc. for suitability of quality of Groundwater.

Article Template

Article Title

Date of Submission: dd/mm/yyyy WhatsApp No. : xxxxxxxxxxx Email: xxxxxxxxxxxxxx@yyyyyyyyyy

Author (s):
(Passport Size Colour Photographs of all)
(Designation, Institution, Country, Email and WhatsApp No of all)

Abstract
The abstract should summarize the content of the entire paper (topic-methodology-database-analysis-results-finding;Word Limit = 300).

Keywords
Give 4 - 6 keywords in alphabetical order, separated by comma.

Body
Arrange the body of the text in the order: Introduction (including statement of the problem, previous work, research gap, purpose, and its significance) - Study Area - Objectives - Hypothesis - Methodology -Manipulation and Analysis - Result and Discussion - Conclusion - Acknowledgment - References - Tables - Figures.

Acknowledgment (if any)
An acknowledgment section may be presented after the conclusion, if desired.

Table
Format: *.doc or *.xls; Captions and Source are must; Maximum Size : Row = (within 25) and Column = 10; Total No. of Tables must be within 4 Full Pages.

Figure (Graphs, Diagrams, Maps and Photographs)
Format: *.jpg; Captions and Source are must; No Border; Dimension: Width = 3.5 inch or 6 inch with legible labels

Note: *While writing, avoid unnecessary capitalization.*

References
1. A reference list MUST be included using the following as a guide.
2. Only cited text references are to be included.
3. References must be numbered and ordered alphabetically.
4. Each reference should be referred to in the text as shown below —

Reference within the Text (examples):
(a) According to Sarkar (2007),
(b) …… (Sarkar, 2009),
(c) …… (Sarkar and Patel, 2011),

General Information

1) The "*Indian Journal of Spatial Science*" is a publication of the "*Indian Society of Spatial Scientists*" with Head Quarter currently housed at "SUMANGAL", 47 Bosepara Road, P.O. Chandannagar, Dist. Hooghly, West Bengal, India PIN 712136.
2) It publishes the "*Indian Journal of Spatial Science*" twice a year with *Summer or Spring Issue* (d.o.p. March 21) and *Winter or Autumn or Fall Issue* (d.o.p September 23).
3) Its editorial board comprises eminent personalities holding positions in academic and research institutions / organizations, and laboratories all over the globe.
4) It reserves the right to revise or modify articles to conform to the journal's style.
5) The views expressed in the article shall however, remain the opinion of the authors, and the editorial board accepts no responsibility for these.
6) Articles which do not strictly abide by the instructions mentioned here are likely to be rejected without further review.
7) Manuscripts should be sent electronically (All authors must register before login in). Only the soft copy in *.doc or *.docx format should be either directly sent to the Managing Editor (editorijss2012@gmail.com) or be uploaded.
8) Tables and Figures must be sent in separate files.
9) Tables and Figure No. must be properly cited in text.
10) Within a few days after submission, the Volume No. and Issue in which it has been booked will be intimated to the author(s), or after the successful submission of a manuscript authors receive an automated confirmation e-mail.
11) Once submitted, articles can not be withdrawn.
12) For additional guidance on any matters not specifically addressed, authors should contact the Editor-in-Chief or the Managing Editor (editorijss2012@gmail.com; ijss.isss1996@gmail.com; etraverse.ijss@gmail.com)

Certification Required

that the work is original of the author(s), that it has not been published before, and that it is not under consideration for publication anywhere else.

Editorial Procedure

Articles submitted to the journal are subject to the following review procedure:

1) A Primary Screening (PSR) is done to find the general suitability of the Article in the IJSS , and also to find 'plagiarised content', if any.
2) The PSR is then sent to the author and for further revision/ modification, if needed.
2) The revised articles are then subject to a double blind peer review process.
3) Articles are accepted, revised (by the authors) or rejected based on the recommendations of the reviewers.

Copyright

In accordance with copyright law, the manuscript must be previously unpublished and not contain substantial portions of previously published material. Permission to reproduce copyright material must be obtained by the authors before submission and any acknowledgments should be included in the submission. Acknowledgment of source and copyright should be given in cases where photographs, data and media are reproduced.

The editorial policy is the responsibility of the Editorial Board, but the Authors' opinions must be/ should be regarded as their own.

Issues of Language

The authors are responsible for presenting the article and the abstract in good English. They are also responsible for proof-reading the original article.

Abstract

The present study aims to determine the land use/land cover features of the Tungabhadra River basin of Kurnool District, Andhra Pradesh, for 2023 using remote sensing and GIS Technologies. The study used the Survey of India topographic maps 57E/1 to 57E/16 and 57I/1 to 57I/5 and the remote sensing data of LISS III, 2023 processing in Arc GIS 10.3 and ERDAS software. Understanding existing land use and land cover in a region is crucial for maximizing land efficiency. It allows informed decision-making in urban planning, agriculture, conservation, and resource management. Accurate knowledge empowers stakeholders to optimize land utilization for sustainable development. The analysis reveals that the study area contains components such as Agricultural land, Built-up areas, Forests, Wasteland, Water bodies, and Transportation. Most of the study area is occupied by agricultural land 77.03%, followed by Wastelands 10.68%, Forest land 4.58%, Water bodies 3.90%, Built-up land 3.53%, and Transportation 0.28%.

Introduction

Land is one of nature's most valuable gifts, and humans perform different activities on it. Sustainable utilization of available land resources determines a region's socio-economic and cultural progress. Land cover refers to the surface cover on the ground, which includes weather, vegetation, urban infrastructure, water rocks, bare soil, or other elements used for identifying, delineating, and mapping purposes. Land use refers to man's activities and the various uses that are carried out on land. Land use involves the manipulation of land's biophysical attributes and the intended purpose for its use.

Understanding the current land use and cover is crucial due to significant environmental challenges such as habitat loss, biodiversity decline, and climate change. The rapid changes caused by urbanization, agriculture, and deforestation put ecosystems and natural resources at risk. Analyzing land use patterns helps inform sustainable development strategies, conservation efforts, and policy interventions to secure a more resilient future. The scope of this analysis ranges from local to global scales, and it involves monitoring changes, assessing impacts, and identifying vulnerable areas. Doing so makes it possible to implement targeted interventions for sustainable land management and adaptation to environmental change. Integrating remote sensing, GIS, and modelling enhances spatial analysis and decision-making. The current land use and land cover significantly shape global environmental, social, and economic outcomes. Managing these dynamics preserves biodiversity, ensures food security, and mitigates climate change impacts. Sustainable strategies promote resilience and adaptability, fostering equitable access to resources, enhancing community well-being, and safeguarding ecosystem health benefits for current and future generations.

Accurate land use information is crucial for properly planning, managing, and monitoring natural resources (Vishwanath, 2014). Effective land use and cover information is crucial for implementing management strategies to meet the rising demands of the growing population for basic human needs and welfare.

(Nagaraju et al. 2016, Veeraswamy, 2019). Land cover mapping is being undertaken at various scales, from local to national to global. Using panchromatic, medium-scale aerial photographs to map land use has been widely accepted since the 1940s. Recently, small-scale aerial and satellite images have been employed for land use and land cover mapping. Land use and land cover are crucial factors in various fields such as hydrogeology and mining, urban planning, agriculture, hydrology, and soil. Accurate land cover identification is critical for various purposes, including global monitoring studies, resource management, and planning activities. It serves as a foundation for change detection and thematic mapping. Land use describes how land apparel is used (for agriculture, residence, or industry). Land use applications require initial mapping and ongoing monitoring to ensure current information on the quantity and type of land use and to detect any changes in land use over time (Haque & Basak, 2017).

Chatterjee (1941) emphasized the importance of studying India's different types of land use cover. He noted that this intricate pattern requires geographical investigation of the physical environment. To this end, he conducted a land use land cover survey in Howrah district and 24 Parganas of West Bengal (Chatterjee 1945, 1952). The study revealed that the district had poor drainage conditions despite having large rivers. It also discussed the impact of soil and climate on land utilization, population pressure on land, trade and transport, nature of land utilization, and agricultural implements. Mukherjee (1967) observed the changing land use pattern in Howrah district and suggested planning strategies for agricultural land use. Roy (1972) emphasized the relationship between land use and agricultural characteristics of the Damodar-Saraswati Doab area. Chatterjee and Jana (1975) studied the pattern of land utilization around Tarakeswar town of Hooghly district.

Singh RB and Dilip Kumar (2012) used remote sensing and GIS to map land use and cover and integrate land management in the Middle Ganga plain. They recommended alternative land use systems and the integration of livestock enterprises with the agricultural system for effective land resource management. In 2014, Sreenivasulu conducted a study using IRS LISS III data to map the land use and land cover of Rajampeta in the Kadapa district. The study revealed a worrying trend of rapid decrease in water bodies and marshy areas and a significant change in land use from agricultural to residential. Additionally, water bodies were converted into marshy terrain and marshy areas into either residential or agricultural land. These findings indicate substantial urbanization and alteration of natural landscapes in the region. In 2017, Gopenaik investigated the land utilization patterns in and around the Dosalavanka watershed in the Chittoor District. Similarly, in 2021, Vinodh Kumar conducted a study on land use and land cover analysis in the Uddanam area of Srikakulam District. Their study revealed that agricultural land occupation was predominant, while uncultivated land was occupied somewhat.

Land use and land cover mapping can be done using satellite sensing data to create a reliable database that includes information on Kharif, Rabi, and Zaid crops, greening of wastelands, surface water bodies, forest vegetation, and other high temporal land-use practices. The National Remote Sensing Agency developed the land use and land cover data in 1989, and it has been updated using visual interpretation techniques recommended by NRSA in 2019.

e and Land cover, Remote sensing, GIS, Tungabhadra River Basin

The Study Area

The study area of the Tungabhadra River basin is in the north-western region of the Kurnool district in Andhra Pradesh, India. It lies between North Latitude 15^0 15'00" to 16^0 0'00" and East Longitude 77^0 0'0" to 78^0 15'00". The area falls within the Survey of India (SOI) Toposheet Nos. 57E/1 to 57E/16 and 57I/1 to 57I/5. The total area of the basin is 6,934 square kilometers. The basin consists of 30 mandals, with 21 mandals fully covered and the remaining nine mandals partially covered. The Tungabhadra River basin receives an average annual rainfall of 670 mm and experiences temperatures ranging from 12°C to 31°C in the winter. Moreover, summer temperatures range from 26°C to 46°C. Agriculture is the primary occupation and main source of livelihood for the people residing in the Tungabhadra River basin. Over 70% of the basin's population is involved in farming. Rainfed agriculture is the most practiced type of farming in the region. The "fallow-chickpea" cropping system is the preferred method for farming by most farm households.

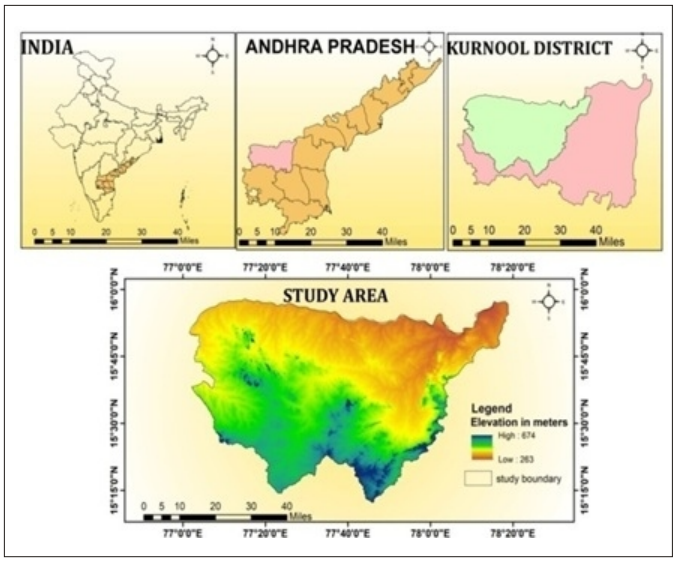

Fig.1 Location map of the Tungabhadra River basin

Objective

This study aims to conduct a comprehensive land use and land cover (LULC) analysis of the Tungabhadra River Basin in Kurnool District, Andhra Pradesh, utilizing remote sensing and Geographic Information System (GIS) techniques.

Database and Methodology

In the present study, we have mainly used two types of data. These are Topographic maps and Remote sensing data. Satellite imagery from the IRS P6 LISS III at a 23m resolution was used to classify land use and cover in 2023. The topographic map 57E/1 TO 57 E/16 and 57I/1 TO 57I/5(1:50,000 scale) is obtained from the survey of India, Hyderabad, surveyed and prepared in 1976; it is converted to digital mode using scanning. The topographic map is georeferenced with longitude and latitudes using the ArcGIS 10.3 software and spatial analyst tools to demarcate the drainage basin. The classification scheme used was developed by the National Remote Sensing Agency (NRSA) in 1995. Visual interpretation techniques were employed to classify features on the satellite images, using a key that helps distinguish features based on patterns, tonal variation, associations, and texture. These data sets

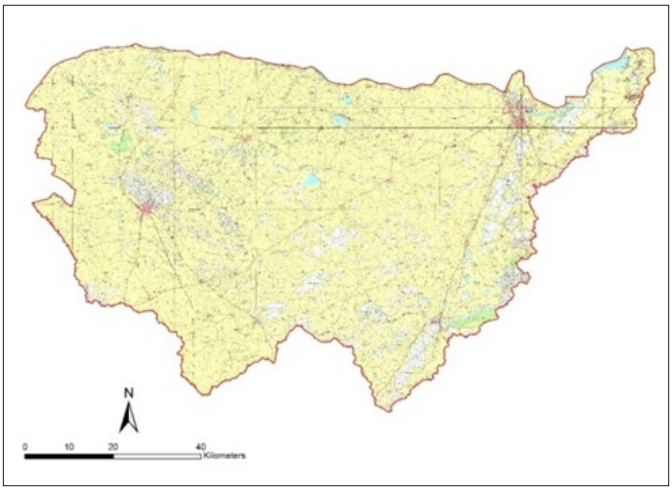

Fig:2: Topographical Map of the Tungabhadra River Basin in Kurnool District

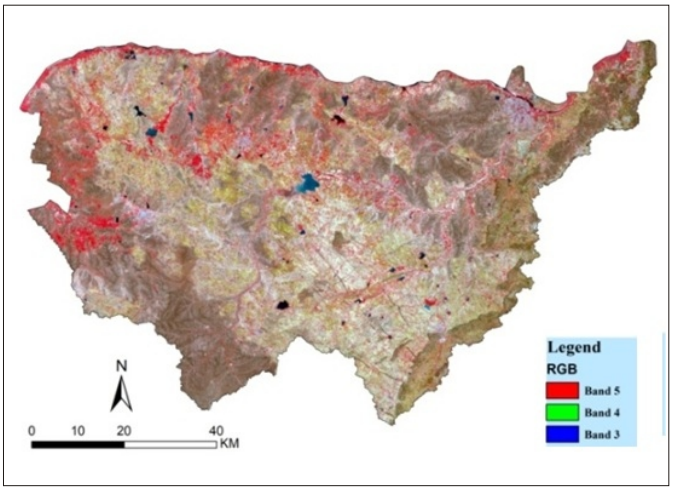

Fig:3: False Colour Composite Map of the Tungabhadra River Basin in Kurnool District

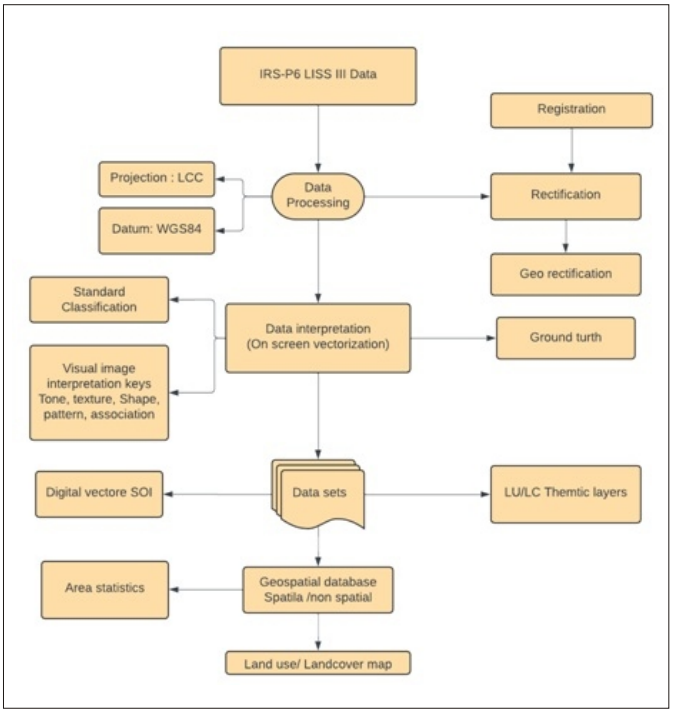

Fig.4. Flowchart of Methodology for LU/LC Map

were imported into ERDAS Imagine, a satellite image processing software, and a false color composite (FCC) was generated. The image interpreter toolbox's layer stack selection produced FCCs for the study area. Georeferencing, subset, mosaic, and projection were performed using ERDAS Imagine 9.0 and ARC GIS 10.3.

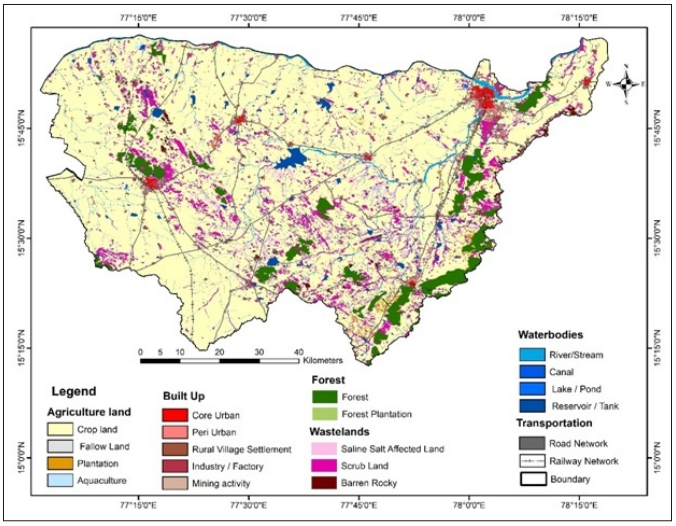

Fig.5: Landuse and Land Cover Map of the Tungabhadra River Basin in Kurnool District

Results and Discussion

Agricultural land

The land use category primarily produces food, Fiber, and other commercial and horticultural crops. It includes land under crops, namely cropland, fallow land, agricultural Plantation, and aquaculture. The agricultural category is the primary category, covering 5341.04 sq. Km (77.03%) during 2022-23.Table.1 & Fig.5

Crop Land: Croplands are typically categorized into Kharif, Rabi, and Zaid crops. Kharif crops, sown during the monsoon season, rely on irrigation rainfall, including paddy, Jowar, maize, chilies, cotton, and others. Rabi crops, planted between October and December, thrive in areas with assured irrigation or residual soil moisture, such as Bengal gram. Zaid crops, cultivated in summer months, primarily in irrigated regions, encompass crops like melons and cucumbers. This classification facilitates understanding seasonal agricultural practices and water management needs in diverse regions, with the total cropland area in the basin is 5279.93 sq. Km (76.15%) during 2022-23. This categorization helps understand the seasonal agricultural practices and water management requirements across different regions.

Fallow Land: Fallow land refers to agricultural areas deliberately left uncultivated for one or more seasons, allowing the soil to recuperate for up to five years. This practice aids in preserving soil fertility and productivity by preventing degradation, erosion, and nutrient depletion. Incorporating fallow periods into crop rotation systems supports sustainable farming, reduces reliance on chemical inputs for weed and pest management, and restores natural balance. With a total area of 13.94 sq. km, representing 0.20% of the land, fallowing plays a crucial role in maintaining soil health and ensuring long-term agricultural sustainability.

Agriculture Plantation: Agricultural plantations encompass

areas dedicated to cultivating tree crops, employing specialized agricultural management techniques. These regions also encompass land use systems integrating the intentional cultivation of herbs, shrubs, and vegetable crops alongside conventional crops, often under irrigated conditions, motivated by ecological and economic considerations. The distinguishing characteristics of these areas include their separability from cropland, which is particularly evident during the rabi/zaid season. Empirical findings for 2022-23 reveal that 43.19 sq. km (0.62%) of land was devoted to plantation crops during this period.

Aquaculture: Aquaculture ponds are areas where fish and shrimp are bred and reared commercially. They are usually located along the coast or in lakes, rivers, and estuaries. This category is mainly found along the coast and occupies an area of 3.98 sq. km (0.06%).

Built-Up Area

These are the areas where people live, work, and communicate with each other. They include buildings, transportation systems, utilities such as water and electricity, and agricultural and industrial areas. These areas are core urban, peri-urban, rural, industrial, and mining/quarry. They cover 244.69 square kilometers, approximately 3.53% of the region's total geographical area. Rural areas account for 1.92% of the total area, more than half of the developed land. Table.1 & Fig.5.

Core Urban Area: Structures, highways, and artificial surfaces cover most of the terrain, encompassing nearly the entire land surface. The built-up-compact class is assigned when the urban structures and transport network (i.e., impermeable surfaces) occupy more than 35% of the surface area. This category occupies 38.10 sq. km (0.55%) and is in urban areas.

Peri-urban Area: Most of the land is covered by buildings, roads, and artificial surfaces, with vegetated areas and bare soil occupying significant but discontinuous surfaces. Between 20 and 40 % of the total surface should be impermeable. This category delineates scattered blocks of residential flats, hamlets, and small villages. It contributes an area of 37.44 sq. km (0.54%).

Rural Village Settlements: Rural settlements have relatively less human habitation than urban settlements, where most people farm. These settlements are categorized as built-up (rural) areas and are associated with non-commercial and allied classes. The rural area accounts for approximately 133.25 square kilometers, representing 1.92% of the total area.

Industrial Area: This class includes non-linear impervious surfaces related to trade, manufacturing, distribution, and commerce. These areas are characterized by human activity in manufacturing and supporting establishments for maintenance. Industrial areas occupy 13.39 square kilometers (0.19% of the total) and are typically found in and around towns.

Mining activity: Mining areas refer to the regions utilized for surface operations to extract valuable ores from the ground. These activities leave a noticeable impact on the landscape, with massive pit mines covering vast areas. The current mining operations are primarily large-scale surface operations that aim to remove economically significant ores. The total area contributed by the active mining operations is 22.51 sq. km, which accounts for only 0.32% of the total area.

Forests

A forest is defined as an area with a tree canopy cover of over 30% and a size greater than 0.5 hectares, characterized by trees reaching at least 5 meters in height. It serves as a vital source of timber and wood products and offers opportunities for outdoor recreation. Forests are pivotal in shaping environmental aspects such as air and water quality, wildlife habitat, climate, and other factors.Currently, the forest cover occupies about 317.63 square kilometers, which is approximately 4.58% of the total land area. Table -1 & Fig.5

Forest Plantation: These are the areas where tree species of forestry importance are grown and managed, especially in notified forest areas. Most of these areas are found in uplands and coastal regions within the notified areas. Many can be identified based on their sharp boundaries. The total area covered by forest plantations is 5.41 sq. km, only 0.08% of the total area.

Wastelands

Wasteland is a term that describes degraded land that can be restored to a vegetative state with reasonable effort but is currently underutilized. This type of land can deteriorate due to a lack of appropriate water and soil management or natural causes. Wastelands can also result from inherent or imposed disabilities, such as location, environment, soil chemical and physical properties, or financial or management constraints. Currently, the total area under this category is 735.59 sq. km, approximately 10.68% of the total land area. Table -1 & Fig.5

Salt-affected Land: These lands have excessive salts (soluble salts, exchangeable saline, or both). If canal irrigation water is not managed correctly, it can lead to salinization. This phenomenon occurs when the groundwater level increases, causing salts to accumulate within the root zone in arid, semi-arid, and sub-humid (dry) environments. Salinization can also occur in coastal regions due to seawater ingress or the utilization of groundwater with high salt content. These lands can also become saline if soils have developed on salt-containing parent materials or have saline groundwater. Coastal saline soils may or may not be inundated by seawater. These lands account for only 120.96 sq. km (1.74%) of the total area.

Scrubland : The scrub is typically found in the elevated regions of hillsides, which are usually surrounded by agricultural lands. These areas have shallow and skeletal soils, which can be chemically degraded. Scrubs dominate the landscapes due to the extreme slopes, severe erosion, and excessive aridity. The scrub can be found in a contiguous or dispersed pattern in small to large areas. The dense scrub is mainly found on hills, while the open scrub is found in foothills surrounded by agricultural lands, which occupy an area of 565.56 sq. km, which accounts for 8.16% of the total land area.

Barren Rocky/Stony Waste: It is mainly found in hilly areas with slopes, rocky outcrops, and stony fragments. The total area under this category is 49.07 sq. Km (only 0.71% of the total area.

Water Bodies

This category includes visible surface water, ponds, lakes, tanks, reservoirs, or flowing water bodies such as streams, rivers, and canals. Depending on the water depth, these areas appear blue to dark blue or cyan on satellite images. The water body category covers approximately 270 square kilometers and represents 3.90% of the basin. Table -1 & Fig.5

Rivers/Streams (Perennial): Rivers and streams are natural water pathways flowing across land, either continuously or intermittently, toward seas, lakes, or other water bodies. They play pivotal roles in the hydrological cycle, shaping landscapes and ecosystems and sustaining biodiversity. Additionally, they facilitate transportation and influence regional climates, marking their significance across ecological, geographical, and geological domains. Rivers and streams represent dynamic forces of nature, carving out valleys, nourishing fertile plains, and providing habitats for diverse aquatic and terrestrial life forms. It contributes an area of 138.12 sq. Km(2.0%).

Canals/Drains: Canals and drains are artificial waterways used for irrigation, navigation, or drainage of excess water from agricultural lands. They are primarily found in coastal plains, covering an area of 21.84 sq km (0.31%).

Tanks/Ponds : Tanks and ponds serve as crucial reservoirs, storing water for irrigation year-round, especially in areas lacking natural water sources like rivers. They enable efficient water management, aiding farmers in optimizing irrigation schedules and minimizing wastage. These reservoirs supplement irrigation supplies during droughts, helping sustain crop growth and mitigate losses. Additionally, they support aquaculture, bolstering food security and rural economies. Overall, creating tanks and ponds significantly enhances agricultural productivity and resilience. This category occupies 5.24 sq. km (0.08%) of the land, highlighting its importance in land use classification and resource management.

Reservoirs/Tanks: Reservoirs, formed by damming rivers, serve diverse purposes like hydropower generation, irrigation, and flood control, while tanks, smaller bodies of water, are mainly for localized irrigation in croplands. Reservoirs are large-scale and cater to multiple needs, whereas tanks, typically found in lowland areas, serve specific irrigation requirements. Both are crucial for managing water resources, sustaining agriculture, and mitigating flood risks across various landscapes. This category occupies an area of 104.79sq. Km (1.50%).

Transportation

The transportation infrastructure in the region is intricately linked with a comprehensive system of roads and railways, facilitating the smooth and effective transportation of goods and individuals. The road network includes significant highways and arterial routes, complemented by an extensive railway system that connects essential destinations. This robust transportation grid is crucial in supporting economic activities, improving accessibility, and fostering regional development. Moreover, continuous efforts to modernize and expand these networks aim to strengthen connectivity and mobility across the region further. This category occupies an area of 19.65sq. Km (0.28%). Table -1 & Fig.5

Conclusion

The Tungabhadra River Basin has diverse land use categories, such as agricultural land, built-up areas, forests, wastelands, water bodies, and transportation infrastructure. The region's agricultural land is essential for food production and economic sustainability, and we need to focus on enhancing agricultural productivity through modern techniques and sustainable practices while preserving fallow lands and promoting aquaculture for diversified income streams. Built-up areas signify urban, peri-urban, rural, industrial, and mining zones, highlighting the region's economic and social development. We need to continue investing in infrastructure, urban planning, and industrial growth, but we should also balance it with environmental conservation and sustainable resource management.

Forests are a significant portion of the Tungabhadra River Basin and are crucial for biodiversity conservation, climate regulation, and recreational activities. We must invest in conservation efforts, afforestation initiatives, and sustainable forest management practices to maintain ecological balance and support ecosystem services. Wastelands present opportunities for restoration and rehabilitation to reclaim degraded lands for productive use. Targeted interventions focusing on soil and water conservation, afforestation, and land reclamation can revitalize these areas and enhance their contribution to sustainable development. Water bodies like rivers, streams, ponds, tanks, and reservoirs are vital for irrigation, aquaculture, and water supply. Conserving and managing water resources involves ensuring sustainability, improving quality, and mitigating human activities and climate change impacts. Transportation infrastructure is pivotal in facilitating connectivity, trade, and economic growth. We must invest in modernizing and expanding transportation networks to enhance accessibility, efficiency, and mobility while minimizing environmental impacts.The findings presented in this report can be used as a foundation for informed decision-making, sustainable land management, and resource planning initiatives to foster environmental conservation and socio-economic development within the Tungabhadra River Basin.

Acknowledgment

I would like to thank the DST Inspire Fellowship for its financial assistance. Additionally, I do express my deep appreciation to Dr. Y. Sujatha, Assistant Professor in the Department of Geography at S. V. University, and Joshi Sai Prakash Chowdary, Research Scholar, for their continuous support and valuable suggestions throughout the completion of this work.

Abstract

The aim of the Present study is to analyze the spatial distribution of agricultural crops in the Tungabhadra River basin of Kurnool district using statistical techniques such as Crop Concentration and Crop Diversification. The study focuses on the mandal level, covering a total of 30 mandals within the basin. The data used in this study is secondary data obtained from the Chief Planning Office of Kurnool District (C.P.O) and the Handbook of Statistics, Kurnool District, for the year 2019-20. A total of seventeen crops were considered for this study. The Bhatia's Location Quotient method (1965) was employed to calculate the crop concentration, while the Gibbs and Martin's Quantitative technique (1962) was used to compute the crop diversification index. To visually represent the cropping patterns across the entire basin, the mandal was chosen as the base unit for areal mapping. Among the seventeen crops analyzed, Cotton (37%), Groundnut (15%), Bengal gram (13%), and red gram (9%) were found to be the most widely cultivated crops in the basin. The diversification of crops was found to be high in three mandals, moderate in fourteen mandals, and low in thirteen mandals.

***Key words*:** Cropping pattern, Crop concentration, Crop diversification, Bhatia's location quotient method, Gibbs and Martin's quantitative technique, Arc GIS 10.4

The Tungabhadra River basin, located in the western part of the Kurnool district, is characterized by its unique agricultural landscape. More than 75% of the region comprises Pedi plains, with 45% of the soil being cotton-rich black soils and 30% being red soils due to its geological connection to granite and gneisses. The primary mode of agriculture in this region is rain-fed, and agriculture stands as the predominant land use. Over 70% of the population relies on agriculture for their livelihoods. However, the agricultural system here is primarily based on traditional practices and operates at a subsistence level due to the limited availability of irrigation facilities and the prevalence of marginal and small landholdings. A significant portion of the working population is engaged in agricultural labour.

In this context, the study of crop concentration and diversification becomes essential to assess the state of crops in terms of their distribution across the area, the number of crops grown, spatial variations, and agricultural practices. [1] brought out the patterns of Crop concentration and Diversification in India. This information is critical for regional agricultural planning [2-3]. Crop concentration refers to the density variation of a particular crop in a specific area at a given point in time, while crop diversification represents the opposite, indicating a balanced mix of crops within a region [4]. Both these aspects not only provide insights into areas dominated by specific crops but also play a pivotal role in bolstering the agrarian economy and aiding in land-use planning [5]. The spatial variations in the degree of crop concentration in the area are influenced by various factors, including topography, climate, hydrology, socio-economic conditions, and technological factors. These interactions shape the agricultural landscape of the region, making it crucial to consider these factors when devising strategies for sustainable agricultural development [6]. The studies Crop concentration and crop diversification has been widely studied and mapped by various researchers in India. Among them who have studied crop concentration and diversifications are [7-17].

MATERIALS AND METHODS

Study area

The study area of the Tungabhadra River basin is in the north-western region of the Kurnool district in the state of Andhra Pradesh, India. It lies Between North Latitude 15° 15ˈ00” to 16° 0ˈ00” and East longitude 77° 0ˈ00” to 78° 15ˈ00”. The area falls within the survey of India (SOI) Toposheet No 57E/ 1 to 57E/16 and 57I/1 to 57 I/5. The total area of the basin is 6,934 square kilometers. The basin consists of 30 mandals, with 21 mandals fully covered and the remaining 9 mandals partially covered. The basin receives an average annual rainfall of 670 mm and experiences temperatures ranging from 26°C to 46°C in the summer and 12°C to 31°C in the winter. The northwestern portion, which includes Adoni, Peddakadubur, Alur, Aspari, Chippagiri, Halaharvi, Holagunda, Pathikonda, Devanakonda, Krishnagiri, Veldurthy, Kodumur, and Kallur mandals, has a desolate appearance with vegetation mostly limited to small pockets of reserve forests. This portion of the basin covers an area of 41,712 hectares, which accounts for

Citation: Appanna B, Sujatha Y. 2024. Geographical study of crop concentration and crop diversification in Tungabhadra River Basin of Kurnool district, Andhra Pradesh. *Res. Jr. Agril. Sci.* 15(3): 756-762.

4.46% of the total geographical area. The terrain in this region slopes from south to north and is drained by the river Hundri, which joins the river Tungabhadra at Kurnool. The soils in the north-western parts traversed by the river Hundri are black cotton, while the south-eastern parts are predominantly pure red soils. Geologically, the basin is underlying by the crystalline rock of the Peninsular Gneissic complex (PGC), which includes the Granitic Gneisses and Granite in the western and southern parts of the basin.

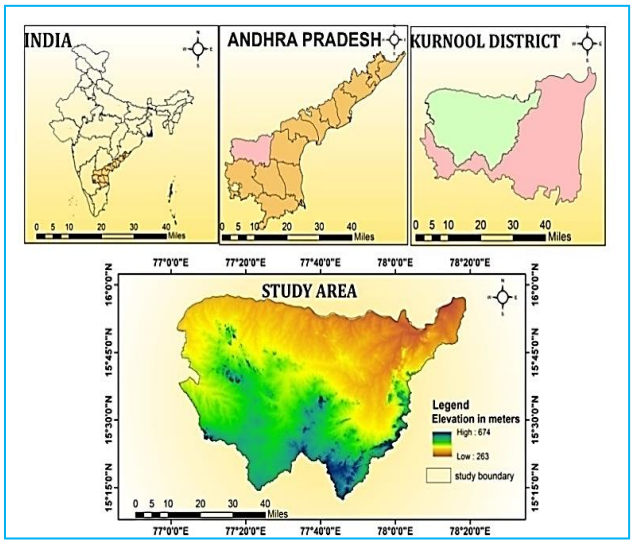

Fig 1 Location map of the study area

The present study utilized secondary data obtained from the Chief Planning office of Kurnool District (C.P.O) and the Handbook of Statistics, Kurnool District, 2019-20. Additionally, relevant information pertaining to physiographic, climate, and soil characteristics was collected from the Andhra Pradesh Satellite Application Centre (APSAC) Manuals and survey reports. To analyze the crop concentration index at the mandal level and its regional variations, Bhatia's Location Quotient Method was employed. This method considers the index values to be directly proportional to the levels of crop concentration.

$$\text{Crop concentration index (CCI)} = \frac{a/b}{a'/b'}$$

Where, a is the area of particular crop in the unit area
b is the total cropped area in the unit area
a' is the area of crop in the entire region
b' is the area of all crops in the entire region

(B). for the delineation of Crop Diversification regions in the study area, Gibbs and Martin Technique (1962) has been used which is Expressed as follows:

$$\text{Crop diversification index} = 1 \frac{\Sigma X^2}{(\Sigma X^2)}$$

Where;
X is the percentage of total cropped area occupied an individual crop.

RESULTS AND DISCUSSION

Spatial patterns of crop concentration in Tungabhadra River Basin of Kurnool district in 2019-20

The index of concentration of paddy, jowar, bajra, maize, total minor millets, red gram, Bengal gram, other pulses, chillies, condiments and spices, fruits and vegetables, cotton, ground nut, sunflower, castor, other oil seeds, tobacco crops for the year 2019-20 has been worked out adopting Bhatia method. The basin comprises of 30 mandals, out of which 21 mandals are fully covered while the remaining 9 mandals are partially covered. Consequently, we have collected complete data from the 9 mandals that were fully covered. so, the total geographical area is 935665 ha [18-19].

Paddy

The total cultivated land area within the basin for the given year amounts to approximately 643,521 hectares, representing 68.77% of the basin's total geographical area. Amongst this, 16,696 hectares are specifically allocated for the cultivation of Paddy, accounting for 2.59% of the overall cropped area. The crop concentration index reveals that there are fourteen mandals with a high concentration of crops, three mandals with a medium concentration, and eleven mandals with low concentration and two mandals are no concentration. Spatial distribution analysis indicates that the northern and north western mandals within the basin exhibit a high concentration of crops. In contrast, the eastern and southern regions of the basin demonstrate a low concentration. Notably, three mandals, namely Orvakal, Miduthur, and Krishanagiri, display a medium level of crop distribution. The Spatial distribution of crop concentration is shown in the (Fig 2, Table 1).

Jowar

The Jowar crop encompasses a total cropped area of approximately 15,319 hectares, representing 2.38% of the overall cropped area. Analysis of the crop concentration index reveals that there are eleven mandals exhibiting a high concentration of Jowar cultivation, while ten mandals display a medium concentration, and nine mandals exhibit a low concentration. Spatial distribution patterns indicate that Jowar cultivation is predominantly concentrated in the north-eastern and south-eastern regions of the basin, with a medium concentration observed in the western and southern areas. Conversely, the central and north-western mandals of the basin exhibit a low concentration of Jowar cultivation. The Spatial distribution of crop concentration is shown in the (Fig 3, Table 1).

Bajra

The present study reveals that the total cropped area under bajra cultivation in the basin is approximately 7023 hectares, which accounts for 1.09% of the total cropped area. The concentration index analysis indicates that the bajra crop concentration is high in eight mandals, medium in seven mandals, and low in twelve mandals of the basin. Notably, the concentration is found to be nil in Kurnool, Miduthur, and J. Bunglow. The spatial distribution analysis further reveals that the concentration of bajra cultivation is high in the north-central and a few mandals in the south, while it is of medium concentration in the central part of the basin. Conversely, the low concentration of bajra cultivation is observed in the eastern, north-western, and south-western mandals of the basin. The Spatial distribution of crop concentration is shown in the (Fig 4, Table 1).

Maize

The present study reveals that the total cropped area dedicated to Maize cultivation in the basin is approximately 24,263 hectares, which accounts for 3.77% of the total cropped area. The concentration index analysis indicates that there are nine mandals with high concentration, two mandals with medium concentration, and fourteen mandals with low

concentration. Additionally, five mandals exhibit no concentration. The spatial distribution analysis reveals that the Maize cultivation concentration is high in the north-eastern part of the basin. Furthermore, the medium concentration is observed in two mandals, namely Kodumur and Yemmiganur mandals, while the low concentration is found in the north-western, central, and western parts of the basin. The spatial variation in maize cultivation within the Tungabhadra River basin indicates significant differences. The Spatial distribution of crop concentration is shown in the (Fig 5, Table 1).

Fig-2 Fig-3

Fig-4 Fig-5

Minor millets

The minor millets exhibit a total cropped area of approximately 3,888 hectares, representing a mere 0.60% of the overall cultivated land. The concentration index analysis reveals a significant concentration of minor millets in nine mandals, a moderate concentration in six mandals, and a low concentration in fifteen mandals within the basin. Spatially, the eastern mandals of the basin exhibit a high concentration of minor millets, while the western and central mandals display a lower concentration. The Spatial distribution of crop concentration is shown in the (Fig 6, Table 1).

Red gram

The red gram crop encompasses a total cultivated area of approximately 60,564 hectares, representing 9.41% of the overall cultivated land within the basin. The concentration index reveals that red gram cultivation exhibits high concentration in eight mandals, medium concentration in seven mandals, and low concentration in fifteen mandals across the basin. Spatial analysis further indicates that the highest concentration of red gram cultivation is observed in the eastern and south-eastern regions of the basin, while the north-eastern region exhibits a medium concentration. Conversely, the western, northern, and central mandals of the basin display a low concentration of red gram cultivation. The Spatial distribution of crop concentration is shown in the (Fig 7, Table 1).

Bengal gram

The Bengal gram crop covers a total area of approximately 82,620 hectares, which accounts for 12.84% of the overall cropped area. The index of concentration reveals that this crop exhibits a high concentration in thirteen mandals, a medium concentration in four mandals, and a low concentration in thirteen mandals within the basin. The spatial distribution analysis indicates that the highest concentration of Bengal gram is observed in the north-eastern and south-western regions of the basin. Additionally, a medium concentration is observed in four specific mandals, namely Bethamcherala, Veldurthy, Holagunda, and Tuggali, within the basin. Conversely, the concentration of Bengal gram is low in the northwestern central and south-eastern parts of the basin. The Spatial distribution of crop concentration is shown in the (Fig 8, Table 1).

Other pulses

The total cultivated area dedicated to other pulses amounts to approximately 6,553 hectares, representing 1.02% of the overall cultivated area. The concentration index reveals that a significant concentration is observed in eight mandals, while a moderate concentration is found in three mandals, and a low concentration is recorded in eighteen mandals within the basin. Notably, no concentration is observed in the Krishanagiri mandal. The spatial distribution analysis indicates that the concentration is high in the mandals located in the north-east and southern regions of the basin. Additionally, a moderate concentration is observed in three mandals, namely Orvakal, Bethamcherla, and Devanakonda, with in the basin. Conversely, the concentration is low in the mandals situated in the north-western and eastern areas of the basin. The Spatial distribution of crop concentration is shown in the (Fig 9, Table 1).

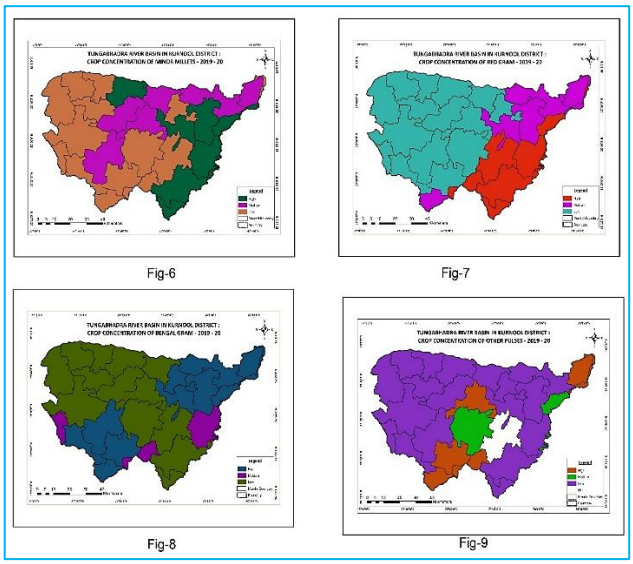

Fig-6 Fig-7

Fig-8 Fig-9

Chillies

The total cultivated area dedicated to chillies crops in the studied region amounts to approximately 7,427 hectares, representing 1.15% of the overall cultivated area. The concentration index reveals that chillies cultivation is highly concentrated in ten specific administrative divisions, moderately concentrated in four divisions, and minimally concentrated in ten divisions within the basin. Furthermore, the spatial distribution analysis indicates that chilli cultivation is predominantly concentrated in the western region of the basin. Additionally, moderate concentrations of chillies cultivation are observed in the mandals of Kurnool, C.Belagal, Veldurthy, and Pagidayala within the basin. Conversely, chili cultivation exhibits low concentrations in the southern and a few mandals in the eastern part of the basin. The Spatial distribution of crop concentration is shown in the (Fig 10, Table 1).

Condiments and spices

The total cultivated area dedicated to the cultivation of Condiments and Spices amounts to 19,230 hectares, representing 2.99% of the overall cultivated area. The distribution of this crop exhibits a high concentration in nine mandals, a medium concentration in twelve mandals, and a low concentration in nine mandals within the basin. Spatially, the condiments and spices crop concentration are notably high in the western and a few eastern mandals of the basin. Additionally, the concentration of this crop is of medium intensity in the northern, north central and southern mandals of the basin. Conversely, the southern mandals of the basin display a low concentration of Condiments and Spices cultivation. The Spatial distribution of crop concentration is shown in the (Fig 11, Table 1).

Fruits and vegetables

The aggregated cultivated land area dedicated to the cultivation of fruits and vegetables amounts to 41,850 hectares, representing 6.50% of the overall cultivated land area. The concentration index reveals that a significant concentration is observed in fourteen mandals, while a moderate concentration is found in ten mandals, and a low concentration is recorded in six mandals within the basin. Geographically, the concentration is spatially prominent in the mandals situated in the north-east, central, and southern regions of the basin. Conversely, the concentration is moderate in the mandals located in the western and eastern parts of the basin. Furthermore, the concentration is relatively low in the western and south-western mandals of the basin. The Spatial distribution of crop concentration is shown in the (Fig 12, Table 1).

Cotton

The total cultivated land area dedicated to Cotton is 40,182 hectares, representing 37.32% of the overall cultivated land area. The concentration index reveals that this crop exhibits a high concentration in sixteen mandals, a medium concentration in seven mandals, and a low concentration in seven mandals within the basin. Spatial analysis indicates that the highest concentration of Cotton is observed in the western, northern, and central regions of the basin. In the eastern mandals, the concentration of this crop is moderate. Conversely, the north-eastern and southern mandals of the basin exhibit a low concentration of cotton cultivation. The Spatial distribution of crop concentration is shown in the (Fig 13, Table 1).

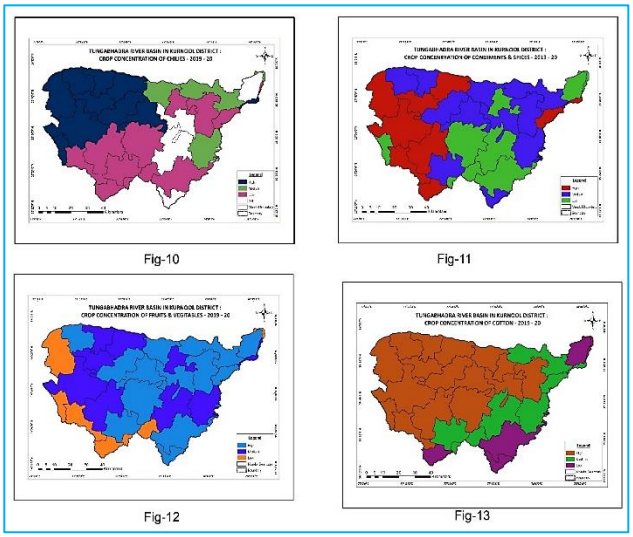

Fig-10 Fig-11

Fig-12 Fig-13

Groundnut

The cumulative cultivated land area within the Ground is measured at 95,239 hectares, representing 14.80% of the overall cultivated land area. The distribution of this crop exhibits a high concentration in nine mandals, a medium concentration in six mandals, and a low concentration in fifteen mandals within the basin. Spatial analysis reveals that the southern and central regions of the basin exhibit a high concentration of ground nut cultivation. Conversely, the western mandals of the basin demonstrate a medium concentration, while the northern, north-eastern, and select south-western mandals exhibit a low concentration of ground nut cultivation. The Spatial distribution of crop concentration is shown in the (Fig 14, Table 1).

Sunflower

The total cultivated area dedicated to sunflower cultivation amounts to 925 hectares, representing a mere 0.14% of the overall cultivated area. The distribution of sunflower cultivation exhibits a high concentration in nine mandals, a medium concentration in three mandals, and a low concentration in twelve mandals within the basin. However, sunflower cultivation is completely absent in six mandals. The spatial analysis reveals that the eastern and certain western mandals exhibit a high concentration of sunflower cultivation, while the central and north-eastern regions of the basin display a low concentration. Furthermore, sunflower cultivation is nonexistent in the north-western and certain southern mandals of the basin. The Spatial distribution of crop concentration is shown in the (Fig 15, Table 1).

Castor

The total cultivated area dedicated to castor is 16,067 hectares, representing 2.50% of the overall cropped area. The distribution of Castor cultivation varies across the basin, with high concentrations observed in ten mandals, medium concentrations in six mandals, and low concentrations in thirteen mandals. Notably, the mandal of Holagunda does not engage in Castor cultivation. Spatially, the southern and central mandals of the basin exhibit a high concentration of Castor cultivation, while the north-eastern part of the basin demonstrates a medium concentration. Conversely, the western and northern regions of the basin display a low concentration of Castor crop cultivation. The Spatial distribution of crop concentration is shown in the (Fig 16, Table 1).

Other oil seeds

The total cultivated area dedicated to other oil seeds is 2,078 hectares, which accounts for 0.32% of the overall cultivated area. The index of concentration reveals that this crop exhibits high concentration in six mandals, medium concentration in five mandals, and low concentration in fourteen mandals within the basin. Approximately five mandals do not cultivate this crop at all. The spatial distribution analysis indicates that the highest concentration of other oil seeds is found in the mandals of Kallur, Orvakal, Bethamcherla, Miduthur, Adoni, and Aspari within the basin. On the other hand, the concentration of other oil seeds crops is medium in C. Belagal, Krishnagiri, Peapully, Holagunda, and Pattikonda mandals of the basin. The concentration of other oil seeds crops is low in the central, north-western, and a few mandals in the eastern and south-western regions of the basin. The Spatial distribution of crop concentration is shown in the (Fig 17, Table 1).

Tobacco

The total cultivated area dedicated to tobacco cultivation in the basin amounts to 3,595 hectares, representing a mere 0.56% of the overall cultivated area. The index of concentration reveals that tobacco cultivation is highly concentrated in five mandals, moderately concentrated in two mandals, and has a low concentration in four mandals within the basin. Approximately nineteen mandals do not engage in tobacco cultivation. The spatial distribution analysis indicates that tobacco cultivation is highly concentrated in the mandals of Kurnool, Kallur, Orvakal, Nandikotukur, and Miduthur. The concentration of tobacco cultivation is moderate in Pagidayala and J.Bunglow mandals. Conversely, the mandals of Kodumur, Gudur, Veldurthi, and Krishnagiri exhibit a low concentration of tobacco cultivation within the basin. The Spatial distribution of crop concentration is shown in the (Fig 18, Table 1).

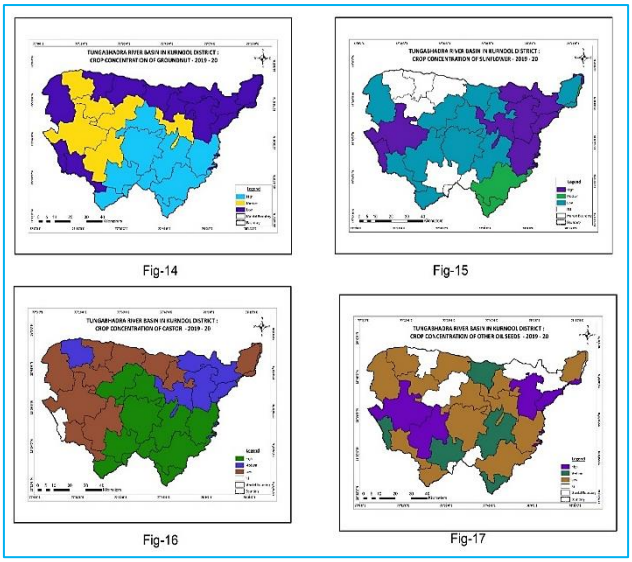

Fig-14 Fig-15

Fig-16 Fig-17

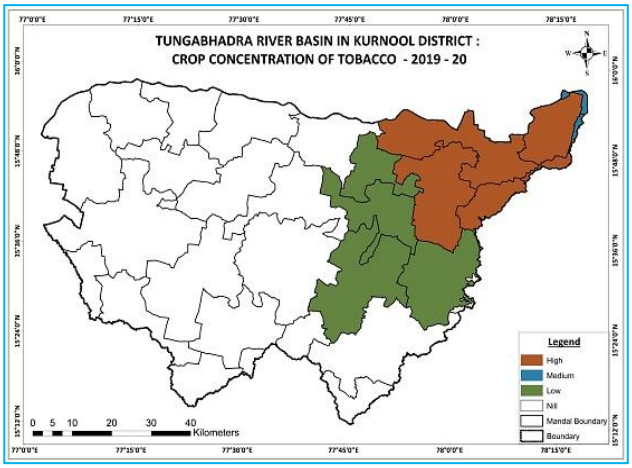

Fig 18

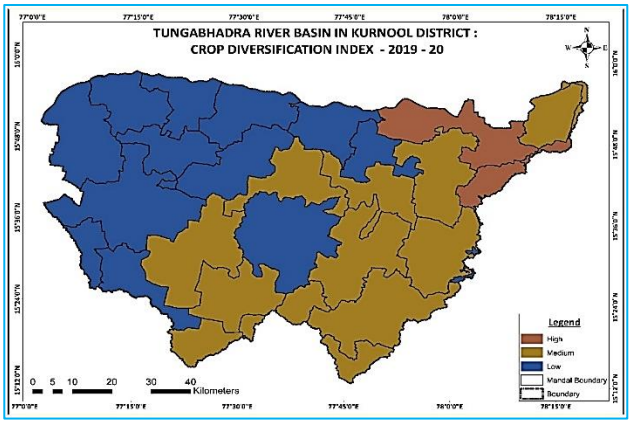

Fig 19

Crop diversification

Crop diversification plays a crucial role in enhancing agricultural productivity and sustainability. Identifying areas with high, moderate, and low levels of diversification can help policymakers and farmers implement targeted strategies to promote diversification and improve overall agricultural outcomes.

Areas with high crop diversification (> 0.80)

High level of crop diversification is found in Kurnool (0.82), Orvakal (0.84) and Miduthur mandal (0.83). Spatially these mandal are in North eastern part of the basin. The Spatial distribution of crop concentration is shown in the (Fig 19, Table 2).

Moderate crop diversification (0.70-0.80)

The mandals in the index exhibit a moderate level of diversification, ranging from 0.70 to 0.80. These mandals include Maddikera (0.80), J.Bunglow (0.80), Kallur (0.79), Veldurthi (0.79), Kodumur (0.77), Pattikonda (0.77), Tuggali(0.77), Gonegandla (0.77), Peapully (0.75), Pagidayala (0.74), Nandikotukur (0.73), Dhone (0.70), Krishnagiri (0.72), Aspari (0.70). The spatial distribution reveals that moderate diversification is observed in the eastern, southern, and a few mandals in the central part of the basin. The Spatial distribution of crop concentration is shown in the (Fig 19, Table 2).

Low crop diversification (>0.70)

The observation of a low level of crop diversification has been made in thirteen mandals, namely Gudur (0.54), C. Belagal (0.69), Devanakonda (0.68), Alur (0.65), Bethamcherla (0.63), Peddakadubur (0.62), Yemiganur (0.61), Mantralyam (0.61), Kosigi (0.60), Adoni (0.57), Nandavaram (0.55), Holagundra (0.49), and Kowthalm (0.39). The spatial distribution of these mandals indicates that they are situated in the north-western and western regions of the basin. The Spatial distribution of crop concentration is shown in the (Fig 19, Table 2).

Table 2 Mandal wise crop diversification index in Tungabhadra River basin of Kurnool district (2019-20)

S. No.	Name of the mandal	CDI	S. No.	Name of the mandal	CDI	S. No.	Name of the mandal	CDI
1	Kurnool	0.82	11	Peapully	0.75	21	Nandavaram	0.55
2	Kallur	0.79	12	Nandikotkur	0.73	22	Mantryalam	0.39
3	Orvakal	0.84	13	Midthur	0.83	23	Alur	0.65
4	Kodumur	0.77	14	Pagidayala	0.74	24	Aspari	0.70
5	Gudur	0.54	15	J. Bunglow	0.80	25	Holagunda	0.49
6	C.Belagal	0.69	16	Adoni	0.57	26	Pattikonda	0.77
7	Dhone	0.70	17	Kowthalam	0.39	27	Devanakonda	0.68
8	Bethamcherla	0.63	18	Kosigi	0.60	28	Tuggali	0.77
9	Veldurthy	0.79	19	Peddakadbur	0.62	29	Maddikera	0.80
10	KrishnaGiri	0.72	20	Yemmiganur	0.61	30	Gonegandla	0.77

CONCLUSION

The spatial variation of major crops in the basin indicates that the contrast is due to topography, climate, socio-economic, and technological factors. It can be observed that the cropping pattern in the Tungabhadra River basin is primarily focused on commercial crops, particularly cotton and groundnut, with food grains such as Bengal gram, red gram, fruits, and vegetables also being cultivated. Cotton is the dominant crop in this region, limiting agricultural diversification. As a result, most of the mandals in the area have a low to moderate index of diversification, with only three mandals, namely Kurnool, Orvakal, and Miduthur, exhibiting high crop diversification. More than 75% of the basin area consists of pediplains, and 70% of the population relies on agriculture for their livelihood. Therefore, crop diversification can be utilized as a tool to improve the economic conditions of small and marginal farmers. The traditional cropping pattern can lead to issues such as decreased productivity and soil fertility. To address these problems, crop rotation, intercropping, and the implementation of micro irrigation technologies such as drip, trickles, and sprinklers are effective measures to enhance soil health, minimize water usage, and reduce soil and water pollution. It is important to carefully manage surface and subsurface water resources and improve irrigation facilities by constructing check dams, percolation ponds, and interlinking canals and tanks to promote good agricultural production. Tungabhadra River basin's agricultural landscape is currently dominated by cotton and groundnut, with limited diversification. By adopting crop rotation, intercropping, and advanced irrigation techniques, and by improving water management infrastructure, the region can enhance its agricultural sustainability and improve the economic conditions of its farming community.

BHERULAL PATIDAR GOVT.P.G. COLLEGE, MHOW

NAAC Accredited "A" Grade

(Affiliated to : Devi Ahilya Vishwavidhyalaya, Indore M.P.)

Welcomes you to the

TWO DAYS NATIONAL WEBINAR

Disaster Management and Modern Communication Medium

(''आपदा प्रबंधन एवं आधुनिक संचार माध्यम'')

Sponsored By: Department of Higher Education Govt. of M.P.

Organized By: Department of Geography

Date 17th & 18th August 2023

E-Certificate of Participation

Certify that Dr.Y.Sujatha, Assistant Professor, Sri Venkateswara University, Dept of Geography, Tirupati, has participated in Two Days National Webinar on "Disaster Management and Modern Communication Medium" Bherulal Patidar Govt. P.G. College, MHOW from 17th & 18th August 2023.

We wish him/her bright and successful future.

Coordinator:
Dr. Rekha Verma
Head of the Department & Professor of Geography
Bherulal Patidar Govt. P. G. College, MHOW

Co-coordinator:
Major Dr. Sanjay Sohani
Professor of Geography

LANDFORMS AND LAND SYSTEMS OF CHITTOOR DISTRICT, ANDHRA PRADESH, INDIA

Dr. K. Bhupal * and Dr. M. Reddi Bhaskara Reddy
Dept. of Geography, Sri Venkateswara University, Tirupati, Andhra Pradesh
Corresponding Author E-mail: bhupalgeography@gmail.com

Abstract
Landforms and Land systems are the collective form of Geomorphology, which contributes more to the ground water and agricultural resources of an area. Ground water and Agricultural resources are basic for the economic prosperity of a country. The various land systems and landforms include Mountains, Plateaus, Plains, Rocky mounds, Escarpments, Domal hills, etc. As the human settlements and activities are generally restricted in regions where mountains dominate, the population in such regions is comparatively sparse. Agriculture is not well developed because of the scarcity of level land, the problem of soil erosion and restricts the ground water flow in the area. Chittoor District, in which the present study is one, is one of the drought prone areas of the State of Andhra Pradesh due to its peculiar location in the leeward side of the Western Ghats. So, in the present paper an attempt has been made to identify various landforms and landsystems and examine how they contribute to ground water resources and allied agricultural activities.

Key Words: *Landforms, Land systems, Undulating terrain, Fluvial plains, Escarpments, Palaeo-channels, Landslides, Lineaments, Geological formations.*

Introduction

Geomorphology is the science of different Landforms. Since each landform has its own characteristic attributes that reveal the conditions that lead to its formation, reconstruction of the physical process that operated or operating in the area can be interpreted based on the identification of landforms in that area. As such geomorphology assumes importance, since it involves interpretation of the origin and dynamics of various Earth's surface features and thus provides essential inputs for evaluation of resources like groundwater, soils and materials; Civil engineering (i.e. for locating suitable sites for the construction of roads, canals, buildings, bridges and dams etc.) and other branches of knowledge which requires understanding of the Earth's surface. It also explains the occurrence of landslides, which is one of the natural hazards of this area. So, the identification and mapping of landforms and land systems is an important facet of geomorphology. They are treated as '**Land Resources'** of the study area. So the aim of the present study is to deciper the various land systems and landforms of Chittoor District keeping in view its role in the formation of soils, ground water flow and agricultural activities.

Study Area

Chittoor District derives its name from Chittoor, its head-quarters town from 1st April 1911. It was located 12° 37' to 14° 8'N and 78° 3' to 79° 55'E. It is bordered by Anantapur, Cuddapah and Nellore districts in the north and by Tamil Nadu State in the south and east and by Karnataka State towards the west. It is situated in the south-eastern fringe of Andhra Pradesh. It is the smallest district in area compared to all the districts of Rayalaseema, covering an area of 15,152 sq.km with a population of in 2001 census, Chittoor had a population of 37,45,875 of which males were 1,889,690 and remaining 1,856,185 were females. Survey of India (SOI) Toposheets bearing the numbers 57K, 57L and 57O on 1:50,000, 1:25,000 scale (1975) formed the base for mapping the region and the satellite imageries of IRS-IC (LISS-IV) (2006) and CARTOSAT for the study of temporal changes that occurred. That was centuries ago. All that has changed. The resources of land and water have become minimum and prosperity has yielded place to poverty. For the last hundred years, the economic history of Rayalaseema, in which the present study is one, has been the very history of droughts and famines mainly due to failure of monsoon and hence today "Rayalaseema is referred to as the "Famine Zone of South India", "the blakest spot on the famine map of India" and the Mezzogiorno" of Andhra Pradesh.

Review of Literature

Many attempts have been made by Geologists, Hydrogeologists, Geographers and other scientists to map various land resources, as they are extremely significant in the formation of soils, soil erosion, ground water occurrence and ground water flow etc. Such a study is also useful to note the areas of landslides, which is one of the natural hazards of this area. In this context, Jayaraju and Bhaskara Reddy (1989) worked much on the identification of Landforms of Chittoor district, basing upon LANDSATS on scale 1:250,000. The "Indian Photo interpretation Institute" at Dehradun and the 'National Remote Sensing Centre" at Hyderabad have been instituted by the Government of India to publish Aerial Photographs and LANDSATS, which are of great use in assessing land resources and landuse. Raghavaswamy and Vaidyanadhan (1981), worked on the Landforms of Visakhapatnam District. Sambasiva Rao and Nageswara Rao (1983), worked more on the Landforms of Godavari and Krishna rivers respectively. Vohara (2008) has published a paper on "Land and water management problem in India" basing upon the availability of landforms and landsystems.

Methodology

Remote Sensing and Geographical Information System (GIS) techniques were adopted to study the Landsystems, Landforms, Landuse, Lineaments and Relief etc. The studies were undertaken critically on Air Photos on scale 1:60,000, Landsats 1:1 million, 1:250,000 and False Color Composits (Fcc's) 1:1 million and 1:250,000. The Survey of India (SOI) Topographical numbers 57K, 57L and 57O on 1:50,000, 1:25,000 scale were used as the base maps.

Geological Formation

The nature and structure of geological formations have many indirect influences on agricultural lands. Geological formations provide the basic materials and structures for the parent materials of the soils. Through the relief, the geological formations have a strong impact on climate and hydrology. Hence, these geological formations were studied in greater depth, which is also a land resource. The rock types met within the district are of diverse types ranging in age from Archaean to recent. Most of the area in Chittoor district is covered by precambrian granites, which are highly magmatised. Cuddapahs and Upper Gondwanas occur as outliers at one or two places. The geological sequence of the district is given below.

Geology Map of Chittoor Distirct

Age	Formation
Quaternary	
Subrecent –alluvium	Gravels, course to fine sands, silts and clays 3 to 5mts. thick.
Recent –Talus	Pebbles and other debris in valley fill areas.
Pleistocene-Laterite	Very hard and compact rocks of fine quartz graining in ferruginous material
Upper Gondwanas	Conglomerates of quartizite pebbles embedded in ferruginous matrix.
Lower Cuddapahs – Nagari	Quartzites with intercalating shales.
Archaeans – Dharwars and other Crystallines	Dolerite Dykes, granites and gneisses with (Porphyritic) feldspar, quartz, mica and hornblende.

RELIEF AND LAND SYSTEMS

The influence of relief on agriculture is multifaceted. Relief is the expression of the interact ion of several different phenomena and processes within the earth Is crust and on its surface. Its forms and dimensions are primarily related to geological formations and to the climate, which have either directly or indirectly acted upon these formation through the process 3f weathering and the concomitant soil formation, So, relief is therefore typically connected with many of the other land resources. Its influence on climate (which was mentioned previously), hydrology and formation of soils (including its negative aspect of soil degradation) are largely dependent upon the nature of the relief. In the present course of investigation the interactions of relief can be observed clearly in *the* formation of soils, climate, hydrology, landforms, drainage and even in the distribution of population, etc. *The* study area lies in a morphologically transitional zone between the interior plateau and the coastal plain. In addition, the north-aouth running Eastern Ghat ranges run in the middle of the district forming its backbone and *the* water divide for many streams, The district slopes down from west to east from an average elevation of about 750 mts,, on the west to about 50

mts on the eastern margin. The district may conveniently be divided into 3 natural divisions as given below.

(a) The Western Hilly Region he Karnataka plateau)

Which comprises isolated hills and hillocks covering the areas of Punganur, Madanapalli and Thamballapalli.

(b) The Central Upland Region

Which comprises three ranges, i.e., (1) Mahendragiri hills covering the areas of Kuppam, Palamaner, Chittoor, Chinnagottigallu and Vayalapadu, (2) The southern portions of Palakonda and Velikonda ranges partly covering the areas of Vayalapadu, Srikalahasti and Chandragir Fort and (3) Nagari hill s covering parts of the areas of Puttur, Nagari and Satyavedu.

(c) **The Plain Region**

Which consists of the valley plains of Bahuda, Pincha, Swarnamukhi, Paler, Arani and Nagari rivers and the coastal plain which lies to the east of Palakondas and Nagari hils.

The relief and land systems of the study area have been delineated based on studies from topographic sheets and false colour composites (F.C.C'S) of LANDSATS. The land systems are delineated based on the assumption that similar grey tones under similar topographic expression reflect similar surface and subsurface moisture conditions, vegetation and organic content of the soils. Tentatively light tones were considered to reflect red soils, colluviurn and sands medium tones to reflect sandy soils to sandy loams on rolling plains and dark tones to reflect sandy, silty , clays on level plains, namely, flood plains, ancient channels, etc. These tones may help in deleneating areas of relative importance in locating groundwater. Field trips have been carried out to various parts of the district to counter check the various systems identified from the study of topographic and related fields. The various land systems identified are:

(1) Hilly terrain

The western part of the district is bordered by a group of hills which belong to Eastern Ghats trending NE-NNE and SE direction, These hills are composed of mainly granites, quartzites and charnockites, The general elevation in these hills range from 1,314 mts. (Horsely Hills) to 1,131 mts. (Tirumala hills) above MSL., with steep slopes exceeding 20 per cent. Field studies in these regions also throw light on differential weathering particularly in the regions where sections of folds are clearly exposed. The general alignment of the disturbed hills in the western and central parts presents that this region in the geological history could have been a major domal structure and this contention has been proved owing to the presence of general 'Radial pattern of drainage' in the district.

(2) Undulating terrain

The central undulating terrain constitutes the hilly slopes, pediments, piedmont plains, valley fills, pediplains and colluvial fans. The slope in this terrain varies from 5 to 25 per cent. The irregularity in the distribution of material in extent and thickness is due to irregular

bed profiles, slope and different geomorphic agents to work. The presence of piedmont plains and colluvial fans with convex facing slopes is an indication of the fact that the rate of accumulation is exceeding the rate of transportation.

(3) Rolling Plains

The slope in these plains is low and varies from 2 to 5 per cent or less than 2 per cent and constitutes of creep built plains, wash plains aid mixed soil plains. The rolling nature of the plains is attributed due to differential rate of weathering, erosion and deposition of materials by gravity stream and wind action. The rolling plains occupy the major part of the district constituting red sandy soils, sandy loans and black soil plainer and reflect low to medium grey tones on the LANDSATS. A few isolated hills/insul bergs stand out prominently in the plains along without crops and give hindrance to agricultural operations.

(4) Fluvial plains

The major rivers during their course of development of river valleys have deposited fine textured alluvial soils on either side of the banks especially on the eastern part and hence this region is 'somewhat plain' in nature, with less than 2 per cent slope, These soils are very fertile and are usually used for cultivation of Rice, Sugarcane, etc., which reflect in dark grey tones on LANDSATS of band 7. As the western and central parts of the district composed of a number of hills and hillocks with exposed outcrops, the panoramic view gives the idea that it is more slopy and undulating. As the rainfall is frackish and erosion of the top soil is more, agriculture in this region is more discouraging and uneconomic. The etymological study of some of the place names in the western part of the district may supports this contention, For example, Rallabuduguru (a place with stones), Bodabandla (etymology Bodibandla, which means 'a barren hill), Ghattu (a hillock), Peddatippa Samudram (Pedda means big, Tippa means rock ‘samudram’ denotes here the 'uncultivable) . In the same way, as the eastern part which is somewhat plain and low lying in nature, some place names like 'pallam' (low lying area) 'Thungundram' (slope of a hill) may supports this view.

3. LANDFORMS (GEOMORPHOLOGY)

The various landforms identified based on grey tonal variation, crustal trends, nature of vegetation, soil texture and drainage characteristics, etc., are classified into broad divisions based on major geomorphic processes involved in their formation. They are

I. Destructional Landforms

Landforms which are grouped to this category owe their origin predominantly by sheet movements of weathered material by erosion and deposition. Exogenetic process, namely, degradation, weathering, mass-wasting and erosion have collectively played important roles in the destruction of these landforms. Field checks to various parts of the district denote that predominantly mechanical weathering process dominates over chemical weathering process due to semiarid nature of climate. Differential weathering in different

parts of the hilly terrain particularly in Horsely Hills in the west and Nagari Hills in the east throw light that structural disturbances might have played significant role in partial destruction of granitic terrain in this part of the district.

(a) Remnants of planation surfaces

Relatively flat topped with gentle slopes with barren surfaces and isolated hills which reflect light to medium grey tons are recognized at an altitude of about 750 m., in the district are presumed to be some of the remenants of planation surfaces. However**,** these surfaces are not associated with lateritic cappings in the eastern part of the study area. Planation surface is an amnibus term and includes Davisian's peneplain, or peneplane concept (Fairbridge, 1968).

Subrahmanyam (1982) while studying the morphology and evolution of Dharmapuri district has identified a series of etchplains at different altitudes where stripping and dissecting are important processes which are involved in the development of these plains. However, such plains are hardly recognized in the study area. A series of profiles taken in E-W direction throw light that there could have been 4 denudational levels, namely, 150-300 m., 300-600 m., 600-900 m., and above 900 m., above MSL, of the 4 denudational levels, it is presumed that levels lying in between 150-300, 300-600 and 600-900 m.**,** clearly depict that these could have been planated surfaces.

Pediments

These are cut rock surfaces with thin to thick veneer of debris. According to Mabbut (1966) they are rarely composed of sub-alluvial semiments over the existing pediments possibly due to lateral deposition of sediments by fluvial action. The pediments are distinctly noticed in and around Tirumala hills and Kuppam hills, The main process involved in the moulding of pediments are back weathering, rain wash, sheet wash and sheet flow. The low angle of pediment and meagre relative relief of residual remnants are presumed to be due to uniform lithology. In a few pockets granites and charnockites are left as residual boulder remenants indicating that the pediments here owe t h e i r origin more too lithological control and differential erosion.

Pediplain

A pediplain is defined as a sum of all pediments, together with residual nubbins (monadnocks) on any flood plains of major rivers (King, 1962). 'Pediplanation is generally accepted as the process responsible for landscape evolution as an alternative to the concept of process of peneplanation. A pediplain is also considered as a plain resulting from coalescence of a number of pediments over a sizeable area developed by the process operating in a semiarid cycle of denudation (Bajada). In the study area, the pediplain is well marked on the northern and western part of the district. They are in continuation of the pedlplain described by Vaidyanathan (1975). These plains in Chittoor District are covered by red sandy soils with a few residual hills and reflect very light in grey tone in the LANDSAT band 7,

Escarpments

An escarpment or scarp is defined as steep rock faces of great length. Two general types are recognized, namely, structural and erosional escarpments. Structural escarpment is a direct product of fault displacement, In the present study area the Tirumala hills, Nagari hills, parts of Kupparn hills and other minor hill ranges show distinct steep escarpments, which run to a distance of about 2 to 5 km. The Tirumala escarpment might have been formed by the structural activity during the development of Tirupati valley upto Nagari nose.

Residual Hills

The multi cyclic residual mountains, namely, exfoliation domes, tors, boulders, domal hills are well distributed on the plains of piedmont colluvial plains, pediments and pediplains. Typical tors and boulders of granitic gneisses are numerous in and around the study area, which causes hindrance to agricultural operations.

Constructional Landforms

The term denudation should in strict sense relate to destructional farms, but has been widely used to constructional forms related to gravitational process could be included under the heading constructive denudational forms to conform to the IGU Classification (Denmek, 1972).

Creep built plains

These are the deposits composed of unassorted material with angular gravel, pebbles and cobbles in a matrix of coarse sand and grit. These creep built plains are partly derived from the bordering hilly terrain and the piedmont colluvial plains by gravity, sheet wash and sheetflow. The thickness of sediments in these plains also varies from 2 to 7 meters and the slope ranges from 2 to *5* per cent. The creep built plains are very widely deposited on the eastern and central parts of the district.

Wash plains

These are stretches of plains next to creep built plains and pediments near to residual hills, with less than 2 per cent slope. These are composed of mixed soils, namely, red sandy and silt soils, which might have formed partly due to overflowing of water over these plains during peak flood periods along major river courses. On the eastern part of the district, soma patches of black soil plains which have been derived from insitu biotite gneisses may also be noticed.

Valley fills

These are the deposits derived from the bordering hilly terrain by gravity, sheet wash and sheet flow. The valley fill deposits consist of fine to coarse textured sandy soils and sandy loams with a few pebbles and cobbles derived from the surrounding hills.

Colluvial fans

A fan is an accumulation of debris brought down by a stream descending through a steep ravine and debounching in the plain beneath, where the debris materials spread out in

the shape of a fan (Denny, 1967). A number of fans are noticeable on either side of Tirupati valley, where plantations of cashew nut and red sanders could be seen. The material is a well weathered colluviurn with stone layers separating successive contributory lobes. In each lobe, the basal horizon is usually constituted by a less weathered stone layer and the upper structure by a very well weathered colluvium.

Flwial plains

The river Swarnamukhi, Arani, and Ponnai have developed canspicuous flood plains which are likely to be inundated during peak flood periods. The plains relatively show law relief, A flood plain is usually built by later deposits with an overlay of vertical accration of flood deposits (Leopold, 1957). The river built plains are utilized for cultivation of rice, sugarcane and banana, Old channels of river Arani could be traced on LANDSAT and due to the change of river courses fluvial terrances could also be traced.

Aeolian deposits

Patches of aeolian sands are recognised in between Madanapalli and Thamballapalli on the piedmont colluvial plains. The extensions of these deposits are very limited.

LINEAMENTS

An analysis of lineaments of the district denotes that NE-SW and NNE-SSW trending lineaments predominate and lie more or less parallel to the structural trends of the hilly terrain. The district possesses hard rock terrain and therefore due importance has to be given to study the lineaments traced from LANDSAT for excavation of groundwater resources. The prominent hills, namely, Mahendragiri, Palakonda, Velikonda, Chandragiri hills, Tirumala hills and Nagari hills are subjected to have low to moderate lineaments, The dominant trend on these parts of the hills is NE-SH and NNE-SSW. Similar lineaments are also traced on plain and upland regions. A careful analysis in the study of name of structural trend, topographic variations and drainage denote that some of the rivers are structurally controlled. For example, the river Poini in Chittoor town which flows to south-east found to be genetically controlled by a fault, lying parallel to the river course. From the study of lineaments, it may be concluded that 14 lineaments lie in between 0°-So to 26'-30° NE in direction having a cumulative length of 314.42 kms., 32 lineaments lie in between 31°-3S0 to 56'-6S0 NE in direction, with a total cumulative length of 823.04 km., and 4 lineaments in between 61°-65' to 71°-7S0 NE in direction with cumulative length of 102-40 km. The total number of lineaments in north-west direction is 22. Out of them, 12 lineaments lie in between 0°-5O and 26O-35O NW in direction with cumulative length of 222.93 km., 10 lineaments lie in between 3b0-40° to 56°-600 NW in direction with a cumulative length of 302.08 km., and only one lineament lies in between 80°-85 NW in direction with a length of 10.24 km. Further studies with the help of air photos and geophysical studies may throw light on the Neotectonics of the district.

Conclusion

The various landsystems, hilly terrain, undulating terrain, leveled plains and fluvial plains and landforms identified with the help of LANDSATS (F.C.Cs) aerial photographs,

geological maps and survey of India toposheet comprise the fluvial landforms(Rapids, waterfalls, pediments, pediplains, terraced plains, riverbuilt plains, flood plains and palaeo channels). The Aeolian lanforms(Tors and mounds, residual hills, taluscones/Talus and Debris slides) structural landforms (Escanpments and landslides) and fluvial-colluviallandforms(Washplainsandcreepbuiltplains).Mostofthe plains in the study area are "creep-built plains', "wash plains", "pediment plains" and "fluvial plains', which hardly supports the agricultural development of the area.

Study Area Map

A comprehensive approach using remote sensing and geographic information systems (GIS) is proposed for the purpose of optimizing water resources in the Tirupati Revenue Division, located in the Chittoor District of Andhra Pradesh.

[1] Dr. V.Charan Kumar Reddy, [2] M. Reddi Bhaskara Reddy (Associate Professor)

Department of Geography, Sri Venkateswara University, Tirupati, Andhra Pradesh, India

Abstract: This research highlights the imperative need for the implementation of strategic water resource management strategies in order to address the increasing water scarcity resulting from population increase, industrialization, and urban development in the specific geographical region under investigation. The proposal suggests the implementation of small-scale projects along the Swarnamuki river belt with the objective of improving water resources for agricultural development in areas with high concentrations of water bodies in the eastern region, as well as addressing anticipated storage deficiencies. By using satellite data and the METRIC approach, this study computes the evapotranspiration (ET) for the Tirupati region, therefore uncovering significant water requirements for crops such as sugarcane. The research provides support for the use of drip and sprinkler systems as new irrigation technologies, emphasizing their potential to effectively reduce water usage. Furthermore, it proposes the use of drip irrigation techniques for sugarcane cultivation and the adoption of the System of Rice Intensification (SRI) for paddy farming as effective measures to mitigate water wastage, emphasizing the need of flexible agricultural approaches. In general, the research offers significant insights into irrigation methods that may effectively reduce water wastage and improve agricultural output, so making a vital contribution to the sustainable management of water resources.

1. Introduction:

Water supplies are being put under strain as a result of population growth, industrialization, and urbanization. Water scarcity is caused by factors such as large fluctuations in annual and inter-annual rainfall, ineffective infiltration, low hydraulic conductivity and storitivity, and high evaporative demand. The development and management of watersheds involve optimal use of water, land, and biomass resources in order to satisfy fundamental necessities in a manner that is environmentally sound. In order to accomplish this goal, runoff and soil loss must be reduced, and infiltration must be increased. Saving water can be accomplished by lowering surface runoff, increasing infiltration rates, and constructing buildings that are suited to their environments. Thematic data can be generated and analyzed with the use of remote sensing and GIS. However, remote sensing provides frequent synoptic coverage of the ground surface, which can be easily researched and represented in GIS. This is a significant advantage. For the purpose of runoff computation, it may include information on land utilization, land cover, and terrain topography (elevation, slope, and drainage network). Therefore, geospatial techniques may be used to select water harvesting sites in order to maximize the availability of surface and ground water for irrigation, domestic usage, and other purposes (Krishnan & Sankararajan, 2021).

The most severely impacted industry across the board is agriculture due to the global water crisis. Seventy percent of the world's freshwater is used for agriculture. Water is essential to the production of food. Since the production of biomass requires a significant amount of water, we could argue that agriculture is both the source of and a victim of water scarcity. The rising demands brought on by population growth come at

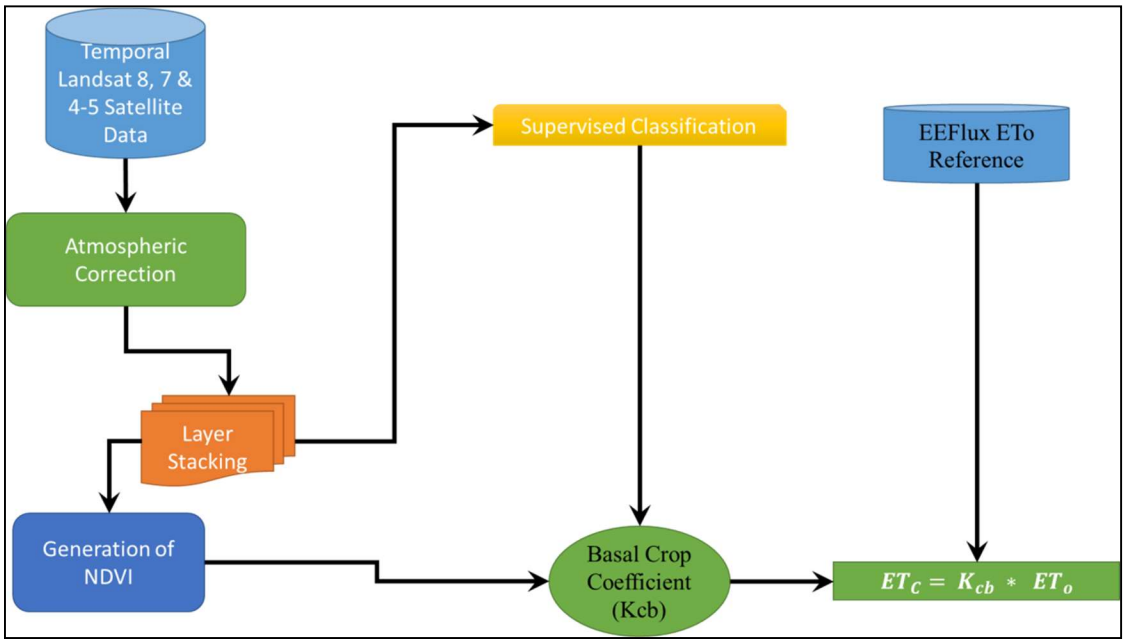
a high cost to the environment. The supply of water and the demand for it, in addition to agricultural practices, could be impacted by climate change and the generation of bioenergy. Agriculture, both rain-fed and irrigated, is impacted by climate change because of the way it alters hydrological regimes and the availability of freshwater (López-Mata et al., 2019). There has been an increase in temperature, as well as increased rainfall variability, semi-arid regions have seen a decrease in precipitation, while temperate regions have seen an increase in rainfall. This has a particularly negative impact on agriculture in tropical and subtropical regions. River runoff and aquifer recharge both have an effect on the amount of water that is available and enhance the demand that humans place on water resources.

Water is scarce in India since the country has 16% of the world's population but just 4% of its pure water supply. Irrigation accounts for the majority of water consumption. Agriculture consumes up to 80 percent of the world's fresh water resources. Irrigation uses up roughly 80 percent of India's available water resources. Given its size of 3.3 million square kilometers and annual rainfall of 1170 millimeters, it is estimated that India has water resources equal to 4,000 cubic kilometers. Over half of this water is lost through processes such as evaporation, percolation, and underground flow to the oceans, which leaves 1953 billion cubic meters (BCM) of water that can be accessed. According to Phansalker and Verma (2005), the amount of water that is available varies, bringing the total down to 1086 BCM. It is anticipated that by the year 2025, the Annual Water Resource will have decreased to 1496 cubic meters, from 2214 cubic meters in 1996. According to (Gulati et al., 2009) findings, just 25 percent of the water resource that is available has been developed

2. Materials and Methodology

Crop evapotranspiration refers to the combined process of evaporation from the soil surface and transpiration from plants. It is a ETc, or reference evapotranspiration, is a fundamental parameter used in the assessment of crop water needs and the development of effective irrigation management strategies. In this study, the estimation of crop evapotranspiration (ETc) was conducted using a combination of satellite-derived reference evapotranspiration (ETo) and the crop coefficient (Kcb) technique. Following the pre-processing of satellite pictures, the estimation of ETc was conducted over the whole of the research region. The FAO-56 technique is often used for calculating evapotranspiration (ETo) and is frequently accessed via the Google Earth Engine Flux (EEFlux) webpage on a daily basis. The estimation of the basal crop coefficient (Kcb) is conducted via the use of the normalized difference vegetation index (NDVI) in relation to Kcb. The procedure for this estimation is elucidated as follows.

2.1 Data Used



In order to accomplish the purpose of the current study, the researchers used several satellite products, supplementary data, and software tools.

Remote sensing data refers to the collection of information about an object or phenomenon from a distance, often using sensors or instruments.

The satellite dataset used in this work is shown in Table 1. Specifically, Landsat 8, 7, and 4-5 data were employed throughout the pre-monsoon and post-monsoon periods of the years 1997, 2008, and 2016.

S. No	Data Type	Date of Acquisition	Resolution	Source
1	Landsat - 8	April 2016 December 2016	30 m	https://earthexplorer.usgs.gov/
2	Landsat - 7	April 2008 December 2008	30 m	
3	Landsat 4-5	March 1997 December 1997	30 m	
4	METRIC (ET reference)	April 2016 December 2016	30 m	http://eeflux-level1.appspot.com/

Table 1 : Details of satellite data products used in this Study

Methodology flowchart

2.2 Ground Measurements

GPS coordinates were collected from study area for the sample sites for accurate identification of particular locations and for further analysis. Ground measurement site map is shown in figure 1.

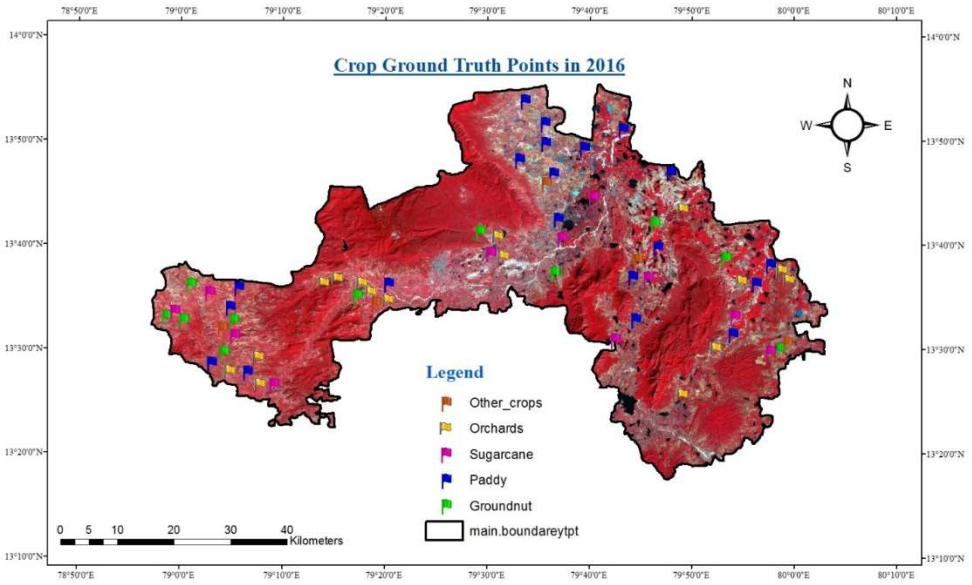


Fig 1: Ground truth measurement site map

2.3 Basal Crop Coefficient

The approaches for determining crop coefficients play a vital role in the estimation of crop evapotranspiration (ETc) and the formulation of irrigation scheduling strategies. The use of generalized coefficients often necessitates the implementation of local adjustments, hence generating inherent uncertainty. Vegetation indices (VIs) obtained using remote sensing techniques, such as the normalized difference vegetation index (NDVI), provide immediate and valuable information on crop variability. There is a scarcity of research available that indicates the potential of vegetation indices (VIs) in accurately estimating the basal crop coefficient (Kcb). The primary objective of this work is to use NDVI measurements in order to estimate Kcb values, with the ultimate goal of enhancing irrigation water management.

$$K_{cb} = K_{cb\max} \frac{(NDVI - NDVI_{min})}{(NDVI_{max} - NDVI_{min})} \quad (1)$$

Where $K_{cb\max}$ is Basal crop coefficient and $K_{cb\max}$ is Basal crop coefficient at effective full ground cover i.e., 1.3 (Hunsaker, 1994)

2.4 Potential/ Reference Evapotranspiration

The use of the METRIC technique, in conjunction with Landsat data and the Google Earth Engine Evaporation Flux (EEFlux), offers a straightforward and precise means of estimating soil water storage

capacity at a spatial resolution of 30m. Notably, this approach does not need the use of soil or vegetation maps. The process of evapotranspiration (ET) is of utmost importance in the hydrological cycle, and it is significantly influenced by sun radiation. The Potential Evapotranspiration (PET), also known as grass reference Evapotranspiration (ETo), plays a crucial role as an agrometeorological parameter, contributing to water balance models and regional evaluations of water demand for rainfed agriculture. The PET product has a precision level ranging from 80% to 90%.

2.5 Crop Evapotranspiration

Crop evapotranspiration (ETc) is defined as the combined process of evaporation and transpiration from a healthy crop, cultivated in expansive agricultural areas with enough water and fertilizer supply (Ding et al., 2013). The estimation of crop evapotranspiration (ETc) plays a crucial role in the calculation of the soil water balance and the development of effective irrigation scheduling strategies. The behavior of ETc is influenced by weather patterns and the state of the crops. Mathematically, the expression for ETc may be formulated as

3. Results and Discussion

3.1 Water Harvesting Sites

Dams block water or subsurface streams. They retain, gather, and store water for equal distribution (Zhang et al., 2023). Worldwide, dams have provided agricultural and urban water for millennia (Chelshi, 2023). The appropriateness of a built dam type in a possible dam site is always questioned. Dam type appropriateness decisions may include trade-offs between various intangibles.

Many methods are used to identify water collecting locations. The most prevalent method, AHP, combined with remote sensing and GIS, provides a worldwide site selection notion (Jayswal et al., 2023). Water harvesting and recharge locations rely on terrain, climate, precipitation, soil porosity, stream order, catchment area, and slope. These characteristics are acquired from various sources, incorporated into the GIS environment using multi-criterion decision making, and the location is chosen. The table below lists water harvesting site selection criteria.

Structure	**Slope %**	**Porosity and permeability**	**Runoff potential**	**Stream order**	**Catchment area (*10^4 m^2)**
Farm ponds	0–5	Low	Medium/high	1	1–2
Check dams	<15	Low	Medium/high	1-4	>25
Subsurface dyke	0-3	High	Medium/low	>4*	>5
Gully plug	15-20	Low	High	1	-
Percolation pond	<10	High	Low	1-4	25-40

Table 2: Selection criterion used for water harvesting sites

3.2 Slope Role

Line slope specifies its steepness and direction. It calculated slope steepness. One of the most essential elements in choosing locations for water collecting structures like check dams is topography steepness and surface runoff potential.

The slope indicates topography, which helps choose water gathering sites. The slope % is defined according to Integrated Mission for Sustainable Development (IMSD, 1995) and Food and Agriculture Organization (FAO, 1977) recommendations for choosing water collecting location. Present area slope classifications are displayed in the figure. CartoDEM (30m resolution) is used to generate % slope map in ArcGIS surface tools.

The slope map provides significant data on the zone's steepness, allowing us to estimate spillover. The region's slope may be divided into seven slant classes: (a) ‘nearly level’ (0–1%), (b) ‘very gentle’ (1–3%), (c) ‘gentle’ (3–5%), (d) ‘moderate strong’ (5–10%), (e) ‘strong’ (10–15%), (f) ‘moderate steep’ (15–30%), and (g) ‘very steep’ (> Slope grades 'nearly level' and 'sensitive' are increasingly suitable for water collection.

3.3 Runoff Generation

Runoff potential depends on DEM slope. According to slope-based criteria for surface runoff production, slope categories will be graded from least to most suited, with steeper slope categories generating more runoff. Runoff potential is classified as ‘moderate’ (200-300 mm), ‘poor’ (100-200 mm), and ‘very poor’ (<100mm).

Proposed aircraft for water resource management research. With above prospects and previous chapter studies of drainage morphometry, land resources, and land use land cover analysis and GIS integration, acceptable and necessary proposals are presented to the research region. Slop is the main source of runoff, thus the Tirupati Revenue Division receives water and soil conservation site suitability maps from slop and existing water resources location study.

Building modest irrigation projects

Apart from its tributaries, the Swarnamuki River runs 80 kilometers in Tirupati Revenue Division. Detailed examination after even shows no irrigation project except Kalyani tributary river. This river has greater discharge than others when it rains more. This project using natural briars is low-cost and beneficial for agriculture and drinking water.

3.4 Building medium and minor check dams

With serious stream network analysis and runoff calculations, a location map was proposed for the constriction of check dams like rock bonds, concrete dams, and earth bounds, especially in the west due to water scarcity. More check dams in that region will help recharge ground water and meet agricultural water needs Farm pound digging and contour ditching from the vast area of research, it is difficult to identify potential locations, but GIS was used to extract barren and fallow land locations suitable for these types of

construction to recharge ground water and expand the agricultural mask. This structure is simple and affordable. This style is also suggested for agricultural land and will assist farmers. Fig.5.5 shows where to build farm pound and contour ditches.

3.5 Other water-saving methods Except from above, this area has additional water saving methods like fallows.

3.5.1. Reusing wastewater Tirupati Revenue Division's largest city produces more urban waste water. Industrial and associated uses of urban waste water may boost indirect agricultural development using waste water cleansing plants. As fresh water can be converted to agriculture, more irrigated land is feasible. However, adopting and managing it is more expensive, so the government may lead water conservation.

3.5.2. Modernized irrigation

Modern drip, sprinkler, and subsurface irrigation minimize water evaporation compared to surface irrigation. It also waters plants straight at their roots. Thus, water waste will decrease and production will increase. According to FAO, converting traditional irrigation methods to modern irrigation will increase the irrigated area by three times. A small attempt was made to irrigate the area with 100% modern irrigation methods using existing water.

The calculation of Evapotranspiration values was conducted during the pre-monsoon and post-monsoon seasons of 2016. This was done in order to provide accurate ground truth data on crop conditions for that specific year, enabling the categorization of crops for the same time period. The subsequent years, namely 1997 and 2008, were analyzed by referring to the District Hand Book and assuming ET values similar to those of 2016.

3.6 Pre-Monsoon Water Requirement

The reference data for evapotranspiration (ET) has been multiplied by the basal crop coefficient (Kcb). The following ranges of evapotranspiration (ET) were observed for the key crops during the Pre-monsoon season of 2016.

S.No	Crop	Range (mm/day)
1.	Groundnut	3.5 to 4.01
2.	Paddy	5.7 to 6.12
3.	Sugarcane	4.16 to 4.438
4.	Orchards	2.271 to 3.246

5.	Other Crops	1.545 to 2.116

Table 3: ET ranges in 2016 pre-monsoon

The Paddy crop exhibits a wider range of ET values during the pre-monsoon period in 2016, with Sugarcane and Groundnut following suit. The range of evapotranspiration (ET) values for orchard crops is quite low due to the prevalence of younger plantings, which constituted around 20% of orchard crops between 2008 and 2016, as reported in the handbook. Younger plants typically need less water during their first growth phases.

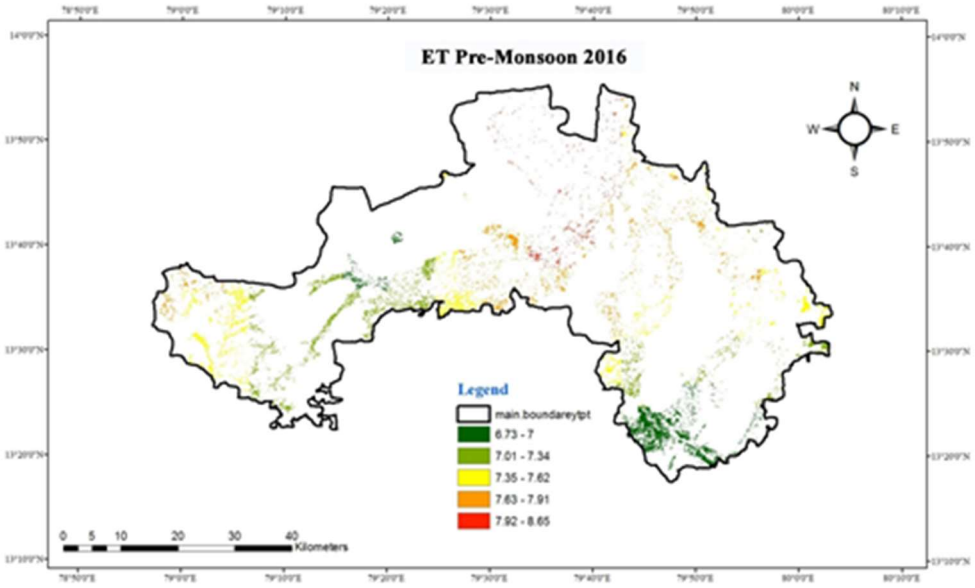

Fig 2. Evaporation in 2016 pre monsoon

The mean values of evapotranspiration (ET) for different crops are as follows: 3.76 mm/day for Groundnut, 5.91 mm/day for Paddy, 1569.14 mm/day for Sugarcane, and 2.76 mm/day for Orchards. The water consumption of the aforementioned crops per hectare, taking into consideration their respective growth periods, is as follows:

S. No	Crop	Growing Period	Average ET (mm/day)	Water requirement (mm/growing period)	Water requirement (cubic meter/ ha)
1.	Groundnut	140	3.76	525.70	5257.00
2.	Paddy	140	5.91	827.40	8274.00
3.	Sugarcane	365	4.30	1569.14	15691.35

4.	Orchards	365	2.76	1006.67	10066.70
5.	Other Crops	90	1.83	164.70	1647.00

Table 4 :Pre-monsoon average ET and water requirement per ha

Sugarcane, a significant agricultural commodity in the nation, necessitates a substantial amount of water over its whole growth cycle, which spans from 12 to 18 months. The specific duration of this cycle is contingent upon the agro-climatic areas, which range from sub-tropical to tropical. According to the Food and Agriculture Organization (FAO), the yearly water demand for this particular crop is within the range of 1500-2500 mm. The estimated yearly water demand for sugarcane in our research region is 1569.14 mm during a period of 12 months.

S. No	Crop	Water requirement (cubic meter/ ha)	Area (Ha) Pre monsoon			Total Water Consumption (Million Cubic meter/Total Cropped Area)		
			1997	2008	2016	1997	2008	2016
1.	Groundnut	5257	21348	419	3326	112.23	2.20	17.48
2.	Paddy	8274	22774	2252	3132	188.43	18.63	25.91

Table 5: Pre-Monsoon Water requirement and Consumption for different crops

3.7 Post-Monsoon Water Requirement

The ET reference data has been multiplied by the basal crop coefficient (Kcb). The following information presents the range of evapotranspiration (ET) values for the key crops during the post-monsoon season of 2016.

S.No	Crop	Range (mm/day)
1.	Groundnut	3.42 to 3.76
2.	Paddy	5.538 to 5.914
3.	Sugarcane	3.84 to 4.564
4.	Orchards	2.193 to 3.346
5.	Other Crops	1.21 to 1.896

Table 6: ET ranges post-monsoon

The range of evapotranspiration (ET) values for the aforementioned crops varies from 1.21 to 5.91 mm/day, with the maximum ET being reported by the paddy*:*

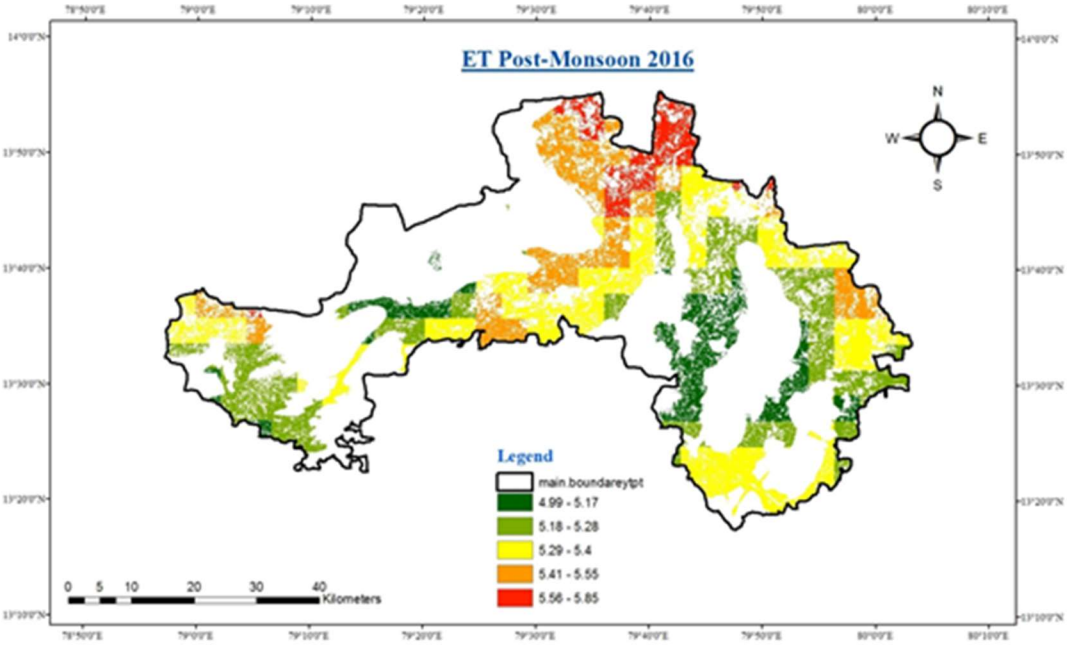

Fig 3. Evapotranspiration in 2016 post monsoon

S.No	Crop	Crop Period	Water Requirement Avg. Value (mm/day)	Water requirement (mm/crop period)	Water requirement (cubic meter/ ha)
1.	Groundnut	140	3.59	502.60	5026.00
2.	Paddy	140	5.73	801.64	8016.40
3.	Sugarcane	365	4.20	1533.73	15337.30
4.	Orchards	365	2.77	1010.87	10108.68
5.	Other Crops	90	1.55	139.77	1397.70

Table 7: Post-monsoon average ET and water requirement per ha

The groundnut crop exhibits an average evapotranspiration of 3.59 in its third position during the post-monsoon season, with a water need of 5026 cubic meters per hectare. The rice crop has the greatest average evapotranspiration (ET) value, whereas sugarcane surpasses it in terms of water

need, with a daily rate of 15331.3 mm/day. This is due to the longer growth time of sugarcane compared to paddy.

S.No	Crop	Water requirement (cubic meter/ ha)	Area (Ha) Pre monsoon			Total Water Consumption (Million Cubic meter / Total Cropped Area)		
			1997	2008	2016	1997	2008	2016
1.	Groundnut	5026.00	26384	20594	20594	132.61	103.51	103.51
2.	Paddy	8016.40	38414	44440	34440	307.94	356.25	276.08
3.	Sugarcane	15337.30	8653	4992	5732	132.71	76.56	87.91
4.	Orchards	10108.68	7563	8463	10402	76.45	85.55	105.15
5.	Other Crops	1397.70	37599	32765	22382	52.55	45.80	31.28

Table 8: Post-Monsoon Water requirement and Consumption for different crops

The water consumption for high water need crops, such as paddy, saw a drop in 2016 as compared to the levels seen in 1997. This occurrence may be attributed to a decline in the overall cultivated land area. Nevertheless, under the provided cropping plan, rice cultivation continued to occupy the top position. The total area under cultivation is mostly allocated to crops other than paddy. However, if the current tendency persists, there is a possibility of further reduction in the cultivated area for paddy, perhaps leading to its replacement by other crops such as orchards, which have shown an increasing trend in cultivated area over the years. Hence, the adoption of System of Rice Intensification (SRI) may be considered for paddy farming, while the implementation of drip irrigation can be recommended for sugarcane production, with the aim of mitigating excessive water consumption in both agricultural practices.

3.8 Other important factors in growth performance of agriculture sector

3.8.1 Fertilizers Consumption

Soil productivity increases with proper fertilizer and manure application. From 2007 to 2016, Tirupati Revenue Division consumed more fertilizers, as seen in Fig. 5.10. Urea, NPK, DAP, and others are used 76, 25, 95, and 200 percent more. Chemical fertilizers have helped farmers grow crops since the 1930s. Chemical fertilizers can cause stream pollution, crop burn, air pollution, soil acidification, and mineral loss. Farmers in these regions should limit fertilizer use and switch to organic farming to naturally increase soil fertility.

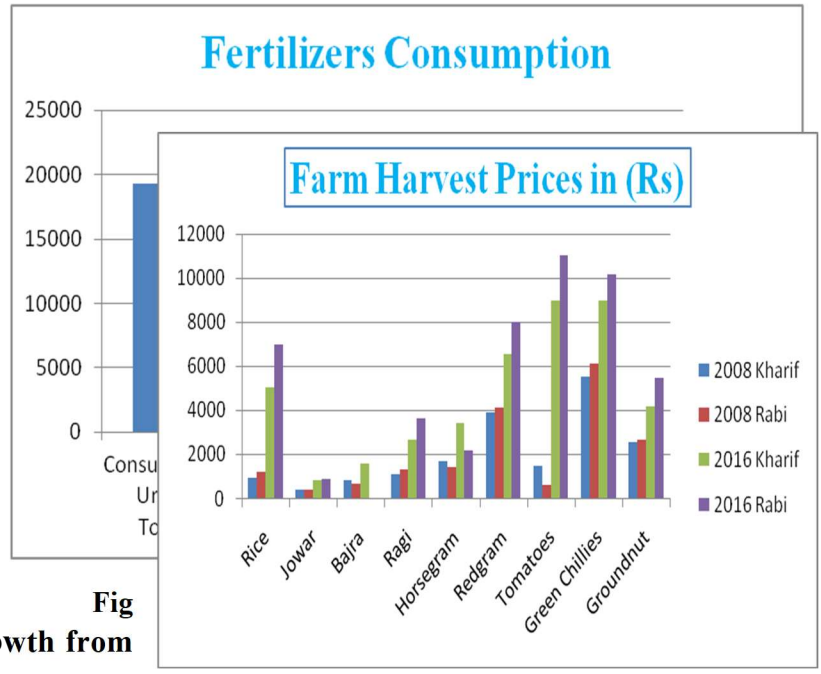

Fig 4. Fertilizers consumption growth from 2007-2016

3.8.2 Farm Harvest Prices

Agricultural harvest prices include product and input prices at various marketing phases. In India, the government's agricultural price strategy tries to ensure growers receive fair prices to stimulate investment and productivity. Annual minimum support prices for main agricultural goods are set after considering Commission on Agricultural Costs and Prices recommendations. In real life, harvesting prices are rising double and triple but minimum support rates are not, so farmers are converting to laborers and losing agricultural land. Fig 5.11 displays agricultural crop harvest prices. Massive increases lead to agricultural deficits. The government will disclose the minimum support price as rates rise.

Fig. 5 Farm harvest prices growth from 2008-2016

3.8.3Agricultural Credit

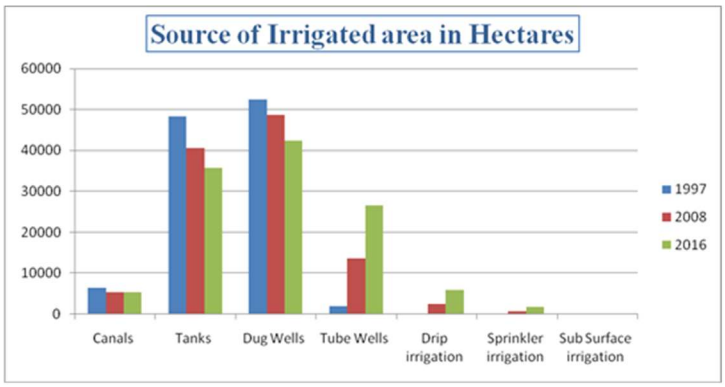
Each economic sector relies on credit. Farmers need credit for investment and working capital. Poor investment credit hinders HYV seed expansion and optimal input use. Like other sectors, agriculture needs easy, appropriate, and timely credit. Even though India has several Rural Financial Institutions (RFIs), the formal banking industry neglects a substantial percentage of the rural population. However, formal Indian banks have rigid credit flows and security-based lending. Additionally, "Long gestation period, lack of educated technical staff to discover potential activity, inadequate eligibility, and security issues contribute to limited loan flow to agriculture. For agriculture financing to move quickly, it must be fixed.

3.8.4 Irrigation system

The Revenue Division's agriculture and allied operations require irrigation, thus the study area's needs must be met. Modern drip, splenkar, and tube well irrigation increases, as seen in Fig.5.12. It is good, but only 10–15% of the remaining land uses traditional methods, which require more water. The irrigation system in this income division has to be changed.

Fig. 6 Irrigation system growth from 1997-2008-2016

3.8.5 Agricultural literacy



Agricultural literacy involves critical thinking and value judgments regarding agriculture's economic, environmental, and social and political impacts. An agriculturally literate person can assess “trade-offs” to people and society from agricultural activities. Decisions and values shape agricultural content. The ability to discuss and make decisions about societal choices shows agricultural understanding.

However, the Revenue division does not have clear statistics on this, and most of the area is rural, and I have seen little agricultural literacy. Thus, farmers must be educated through street performances, night schools, and other techniques to use technology immediately.

3.8.6 HYV, SRI and Mechanization

Modern methods and technology including high-yielding variety (HYV) seeds, tractors, irrigation infrastructure, herbicides, and fertilizers transformed Indian agriculture into an industrial system during the Green Revolution. Mostly found by M.S. Swaminathan. The Green revolution, started by Norman Borlaug, used agricultural research and technology to boost output. Implementation of high yields variety is not complete in study area.

The System of Rice Intensification SRI maximizes farmers' land, labor, and capital returns by lowering their seed, water, and labor needs. This boosts their incomes and helps the environment. SRI plants are resilient to water stress, storm damage, pests, and diseases, which is needed as climate change threatens. This skill may grow in importance. According to the divisional agriculture officer interview, the revenue division has practiced fewer than 20 to 30 hectors of SRI during the past five years. Thus, ground-level technological deployment is crucial for water and agricultural sustainability.

The income division is improving as mechanization continues, but the percentage is low. According to the district statistical handbook, the improvement from 10 years is only 15 to 20% in all types of mechanization. The research region did not properly implement technological mechanization including harvesting machinery and cultivator’s machinery save for land ploughs and electrical pump sets.

3.8.7 Agricultural research staff and centers

The study region had 1–2 agricultural staff per mandal and little technical staff, who were mostly involved in administrative tasks. Most of the study area lacks time to solve basic difficulties. The Southern Zone headquarters, Regional Agricultural Research Station (RARS), Tirupati, is one of two research stations in the study area. The station is 7 kilometers from Tirupati on the Tirupati–Chittoor route. The station was founded in 1979 to research groundnut and groundnut-based agricultural systems, soil and water management, pulses, biofuels, watershed management, and fodders. By 2011, RARS, Tirupati had established Agricultural Polytechnic College in addition to research. Institute of Frontier Technologies was founded in RARS, Tirupati with modern infrastructure and lab facilities to explore biotechnology, bioinformatics, nanotechnology, bio control, soil and water analysis, and quality analysis. The university and Tirupati's best labs are at this institute. Another research station is Krishi Vigyan Kendra, Vanasthali, in Renigunta mandal near Karakambadi. Has district-level Farm Science Centers created by the Indian Council of Agricultural Research (ICAR), New Delhi to speed up technology transfer to farmers. These centers transfer cutting-edge agricultural technologies to end users to boost production and productivity. It collaborates with other agencies. Farmers are interacting with both research sites and answering their agricultural questions. Research is also being implemented locally.

4. Conclusion

In conclusion, the research emphasizes how urgently the study region requires strategic water resource management, in particular as a reaction to the concentrated distribution of current water bodies in the eastern side and the expected gap in water storage projects. The plan that has been presented places an emphasis on the building of modest projects along the Swarnamuki river area. The goal of the strategy is to strengthen water resources in order to facilitate increased agricultural production.

In addition, a technique that is based on remote sensing is used in the research to estimate the amount of evapotranspiration (ET) that occurs in the Tirupati Region. The use of the METRIC method makes it easier to calculate ET values for a variety of crops throughout the pre-monsoon and post-monsoon seasons in the year 2016. The results highlight the enormous water needs of crops such as sugarcane, calling for novel irrigation techniques such as micro-irrigation, with drip and sprinkler systems displaying significant water consumption savings. The findings also call for innovative irrigation strategies such as micro-irrigation.

According to the findings of the study, there is a possibility that excessive water consumption may be reduced by applying the System of Rice Intensification (SRI) for paddy farming and by boosting drip irrigation for sugarcane. In addition, the research identifies fluctuations in farmed areas across various types of crops, which indicates the need for adaptable agricultural techniques. In general, the study produces useful insights for the management of water resources in a sustainable manner, and it argues for the use of contemporary irrigation practices in order to improve water usage efficiency and agricultural yields in the area.

Abstract

This research utilizes remote sensing techniques and incorporates NDVI-based classification methods to estimate crop evapotranspiration (ETc) in the region of Bagpath, located in Western Uttar Pradesh. The approach employs NDVI profiles to accurately map sugarcane-wheat and rice-wheat cropping systems, achieving an accuracy of 86.86% for Kharif crops and 79.72% for Rabi crops. The potential evapotranspiration exhibits seasonal variations, characterized by significant peaks in Kcb values between the months of September and February for both systems. The research examines the variation in ETc, ranging from 3.09 to 6.87 mm day−1, throughout the period of June 2017 to April 2018, with a specific focus on the water requirements for cultivating sugarcane. The dynamics of water stress, as shown by WS_LSWI data, exhibit a correlation with the various phases of crop development, therefore emphasizing the influence of harvesting operations on the levels of water stress.

1. Introduction

Agriculture has significant importance across all economic sectors due to its susceptibility to water constraint. At present, the agricultural sector is responsible for around 70% of the total worldwide freshwater withdrawals. Water has a pivotal role as an essential element in the process of food production. Given the substantial water transpiration demands associated with biomass production, it would not be inaccurate to assert that agriculture serves as both a catalyst and a casualty of water shortage. The exponential increase in population has resulted in significant environmental consequences due to the escalating demands placed on natural resources. The potential effects of climate change on water supplies and water demand, as well as the influence of bioenergy generation on agriculture, are subjects that now lack certainty. Climate change has the potential to modify hydrological patterns and the accessibility of freshwater resources, hence affecting both rain-fed and irrigated agricultural practices (FAO, 2008; FAO, 2011a). There has been seen an augmentation in precipitation levels within temperate regions, along by a decline in precipitation within semi-arid areas. Additionally, there has been noted a heightened variability in the distribution of rainfall, coupled with an overall rise in temperature. The aforementioned factors have a distinct influence on agriculture in tropical and sub-tropical regions. Changes in runoff in rivers and recharging of aquifers have a significant impact on the availability of water, hence exacerbating the strain on water resources caused by human activities.

India has a significant scarcity of water resources, as it accommodates around 16.0 percent of the global population but possesses just 4.0 percent of the available fresh water suitable for use. The irrigation industry is the largest consumer of water resources. Approximately 80% of the global water resources are allocated for the purpose of irrigation. In India, irrigation accounts for almost 80% of the used water resources. The projected water resources of India amount to 4000 cubic kilometers, based on the country's geographical

size of 3.3 million square kilometers and an average annual rainfall of 1170 mm. Approximately half of the water undergoes various processes such as evaporation, percolation, and subterranean flows towards the seas, resulting in a loss. Consequently, only a total of 1953 Billion Cubic Meters (BCM) of water is accessible. According to Phansalker and Verma (2005), the presence of water is subject to temporal and spatial fluctuations, resulting in a further reduction to 1086 BCM. According to estimates, the Annual Water Resource, which measured 2214 cubic meters in 1996, is projected to decrease to 1496 cubic meters by the year 2025. According to Gulati et al. (2005), the Developed Water Resource (DWR) accounts for about 25% of the total accessible water resource.

Low water availability limits plants. Stomata regulate plant water, oxygen, and carbon dioxide flow. Water stress causes stomata to shut to save water, limiting the oxygen, water, and carbon dioxide exchange route and decreasing photosynthesis (Porporato et al., 2001). Thus, water stress affects leaf development more than root growth because roots can adjust. Reduced photosynthesis due to water scarcity reduces crop growth and development. Soil moisture, canopy temperature/evapotranspiration (ET), leaf water content, and LWP affect crop water stress.

Water stress detection helps farmers reduce output losses. Remote sensing and ground-based methods may identify water stress.

Traditional stress assessment methods include predawn leaf water potential (Dixon, 1914), leaf pigment concentration (Lichtenthaler, 1987), leaf chlorophyll fluorescence (Muller, 1874) and ET (Priestley and Taylor, 1972). Predawn leaf water potential estimation employs pressure chamber. This method has measured tree and shrub water relations for 40 years. Manual operation is sluggish and laborious. Leaf water content approach analyzes plant water status by measuring relative leaf water content. Most plant water is in mesophyll cells. The ratio of fresh, dry, and turgid leaf weights determines relative leaf water content. This approach is time-consuming since the water potential difference between stressed and non-stressed plants is largest in the morning. Leaf pigment concentration approach assumes plant pigment concentration changes with species, phenology, and natural and human stress. Chlorophyll levels are higher in healthy plants and lower in stressed ones. Traditional chemical methods involve destructive sample and time-consuming laboratory studies, whereas chlorophyll meters are simple, portable, and fast. Leaf chlorophyll fluorescence is being employed to study photosynthetic equipment. This approach employs a portable optical equipment and fluorescence meter. Photosynthesis is dependent on light, water, and nutrients, which cause plant stress. Thus, this device is a useful diagnostic of plant stress because Chlorophyll fluorescence changes before tissue degradation is noticed in plants, allowing stress to be diagnosed before physical damage. The downside is that this method does not produce commercial instruments. Plant ET is measured with lysimeters.

All ground-based measurements can quantify plant water stress at ground level or local regional level, but not at large geographical scales like remote sensing. Either ground measurement can ground truth remote sensing applications.

Remote sensing for plant and environmental research became popular in the 1980s.Remote sensing provides accurate, quantitative, and timely crop condition data at a lower cost than field approaches (Shen et al., 2009). Remote sensing detects crop growth, stress, and assists agricultural development decisions (Shen et al., 2009). The spectral characteristics of vegetation are determined by leaf internal structure and elements like water, nitrogen, cellulose, and lignin absorption and scattering. Leaves' cellular structure and water content are identified in near and mid-infrared, while their colors are recognized in visible band.

Chlorophyll and water content are key plant stress indicators. Stressed flora has less chlorophyll, which affects leaf pigment light absorption. Therefore, it directly impacts plant spectral signature by lowering

green band reflection and increasing blue and red band reflection, modifying normal plant spectral signature. Thus, Visible, Near Infrared (NIR), SWIR, and TIR bands may detect water stress. Vegetation water stress index (VWSI) and Land Surface Wetness Index (LSWI) are SWIR and NIR indices (Ghulam et al., 2007), while Crop Water Stress Index (CWSI) and Water Stress Index (WSI) are TIR indices.

Precision agriculture depends on irrigation scheduling to avoid water stress and maximize production under restricted water circumstances, hence satellite monitoring of vegetation water stress is crucial. This research used optical data to diagnose sugarcane water stress in Bagpath, western UP.

2. Study Area

The study area includes Bagpath, located in Western Uttar Pradesh. The Western U.P region makes a significant contribution to the overall food grain output, accounting for 34 percent at the state level and 6 percent at the national level. The prevailing agricultural produce in this area is sugarcane.

The research region is situated within the latitudinal range of 28.8 degrees to 29 degrees and the longitudinal range of 77 degrees to 77.5 degrees. The western region is geographically demarcated by the presence of the Yamuna River, which serves as a natural boundary separating it from the neighboring states of Haryana and Delhi. The research was carried out in the Bagpath district located in western Uttar Pradesh.

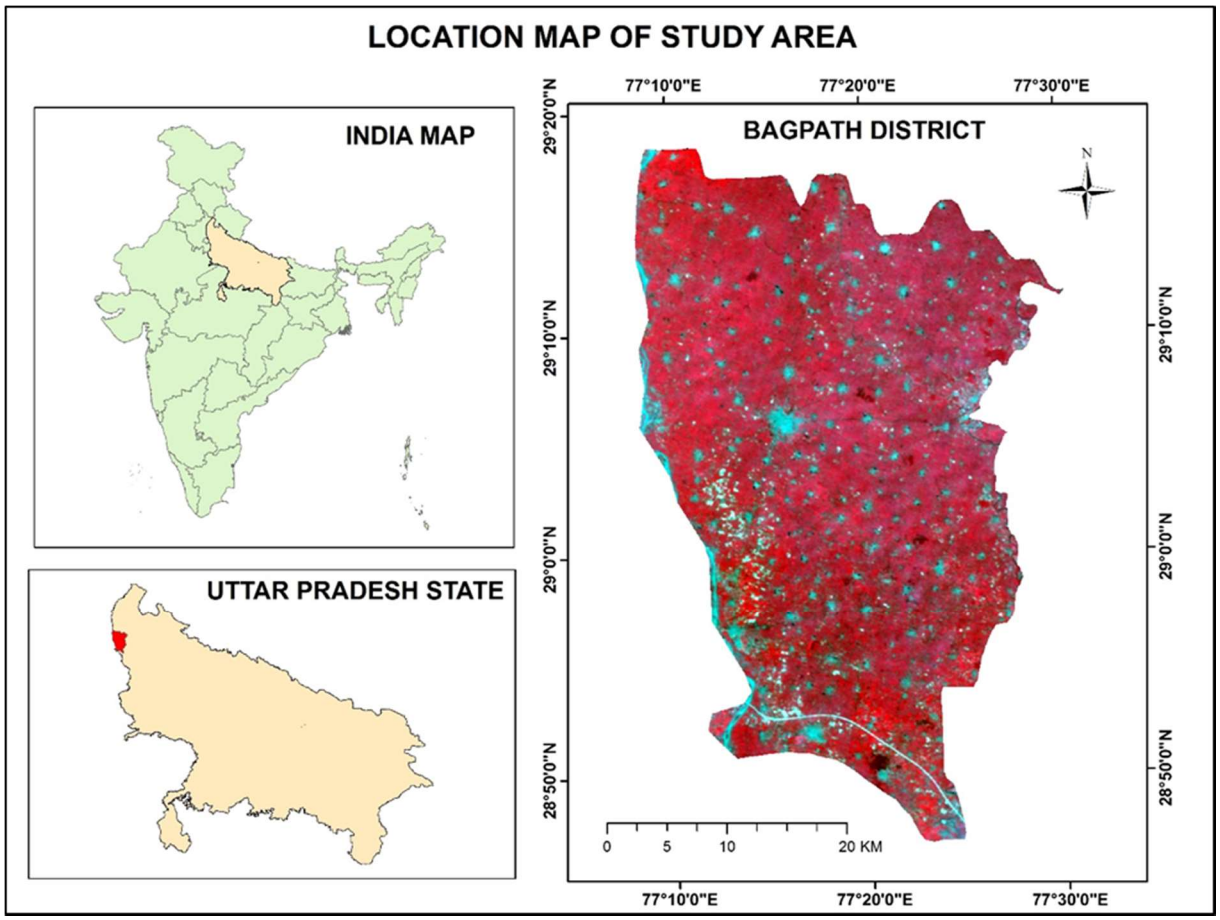

Fig 1. Location Map of the study area

2.1 Soils

Western UP soil is coarse-to-medium alluvium and somewhat alkaline. Their dark gray color indicates considerable organic matter. Loam and silty clay loam cover much of the terrain. 2016 (Nitika et al.)

2.2 Farming Method

Farmers' main business is crop production. This area also farms dairy. Agro-horticulture and agro-forestry are other growing agricultural industries in this area. Sugarcane dominates this region's commercial crop. Due to delayed sugarcane harvesting, wheat field preparation begins in November and lasts until the second week of December. Over 90% of land is irrigated wheat, which receives 4–5 irrigations. 2016 (Nitika et al.)

3. Materials and Methodology

Evapotranspiration of crops ETc provides the foundation for agricultural water needs assessment and irrigation control. This study evaluated ETc using satellite-derived ETo and Kcb. ETc was calculated for the whole research region after satellite image preprocessing. ETo is most often calculated using the FAO-56 technique, which is retrieved daily from MOSDAC. NDVI is used to determine the basal crop coefficient Kcb, as detailed below.

3.1 Data Used

Satellite products, supplementary data, and software were employed to fulfill the study's goal.

3.2 Remote sensing data

Table 3.2 lists the satellite dataset utilized in this investigation.1. AWIFS data was unavailable in February, March, and April 2018, hence Sentinel data was utilized.

S. No	Data Type	Date of Acquisition	Resolution
1	Sentinel-2A	25th April 2018 26th March 2018 14th February2018	10 m (Resampled to 56 m)

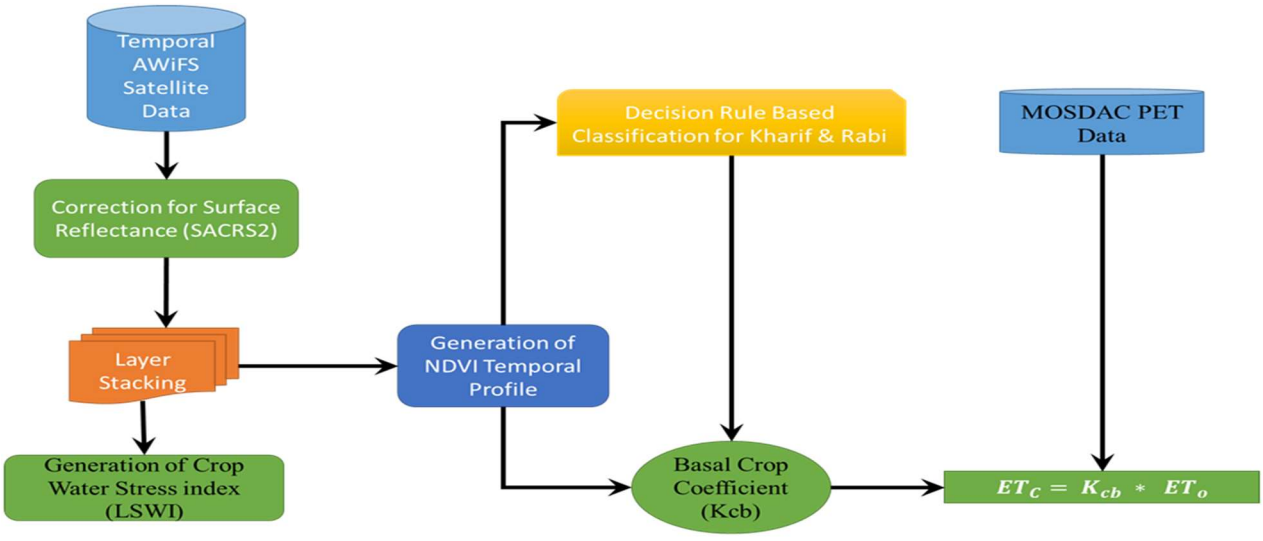

Fig 2. Methodology flowchart

3.3 Basal Crop Efficient

Estimating crop ETc for irrigation scheduling using crop coefficient methods is common. Generalized crop coefficient curves in the literature only estimate ETc for "optimum" crop conditions within a field, which must be modified for local conditions and cultural practices and adjusted for seasonal crop and weather variations. Thus, generalized crop coefficient uncertainties may lead to ETc predictions that are considerably different from real ETc, which might lead to poor irrigation water management. Crop attributes like percent cover and leaf area index may be modeled using vegetation indices (VIs) to quantify real-time crop fluctuations from remotely-sensed VI measurements. VIs can also predict the basal crop coefficient (Kcb) for maize and cotton, according to limited studies. This study estimated Kcb using NDVI measurements.

$$\boldsymbol{K_{cb}} = \boldsymbol{K_{cb\,max}} \frac{(\boldsymbol{NDVI - NDVI_{min}})}{(\boldsymbol{NDVI_{max} - NDVI_{min}})} \qquad (1)$$

Where $\boldsymbol{K_{cb\,max}}$ is Basal crop coefficient and $\boldsymbol{K_{cb\,max}}$ is Basal crop coefficient at effective full ground cover i.e., (Hunsaker, 1994)

3.4 Evapotranspiration potential

INSAT 3D is a geostationary meteorological satellite launched in 2013 as an exclusive INSAT spacecraft. This radiometer has four bands: wide VIS (0.52-0.75), SWIR (1.55-1.70), MIR (3.8-4.0), WV (6.5-7.0), and thermal TIR1(10.2-11.2), TIR2 (11.5-12.5) with 19 sounder channels. VIS and SWIR have 1 km x 1 km spatial resolution, whereas MIR, WV, and two thermal IR bands have 4 km x 4 km. INSAT Meteorological Data Processing System (IMDPS) automates ‘full-globe’ and ‘sector’ data products in all bands at half-hour intervals at 4 km spatial resolution. Daily purchases are limited to 48.

Evapotranspiration (ET) drives the hydrological cycle. ET is unique in its position as a link between the energy and water cycles. Solar radiation, wind speed, air temperature, and vapour pressure deficit affect ETo. Solar radiation is the most sensitive, affecting ETo variability by 60-70%. PET, also known as grass reference ETo, is the quantity of water transferred per unit time to atmosphere from a water-non-limiting surface covered with evenly and actively growing short grass like Alfalfa. ETo is the atmospheric evaporative demand for a given climate. Water stress results from moisture deficiency. Reference Evapo-transpiration is a hydrological and agricultural variable. It is a crucial input in soil water balance models together with precipitation. Many of these models use daily or hourly evapotranspiration data to predict plant water needs. The regional water demand would vary by agroclimatic conditions and agricultural season. Space rainfall and ETo may enable rainfed agriculture monitor water shortfall and excess throughout growing season. PET product accuracy is 80-90% (INSAT-3D Manual, 2015).

3.5 Crop Evaporation Transmission

Crop ETc is the evapotranspiration of a disease-free crop produced in wide fields with plenty of water and fertilizer (Doorenbos and Pruitt, 1977). Calculating soil water balance and irrigation schedule requires ETc estimation. Weather and crop conditions determine ETc. ETc is mathematically represented as $\boldsymbol{ET_C = K_C * ET_O}$ (2)

Kc is the crop coefficient, which varies by crop and growth stage, and ETo is the reference crop evapotranspiration.

3.6 Land Surface Wetness Index

LSWI assesses stress using NIR and SWIR. This measure is sensitive to soil background and total vegetation liquid. LSWI was estimated using this equation:

LSWI=NIR-SWIR/NIR+SWIR (3)

Water stress scalar (Ws) was calculated using estimated LSWI (Xiao et al., 2005).

$$W_S = \frac{1-LSWI}{1+LSWI_{max}} \quad (4)$$

Where LSWI is pixel value and LSWImax is maximum pixel LSWI value for growth season.

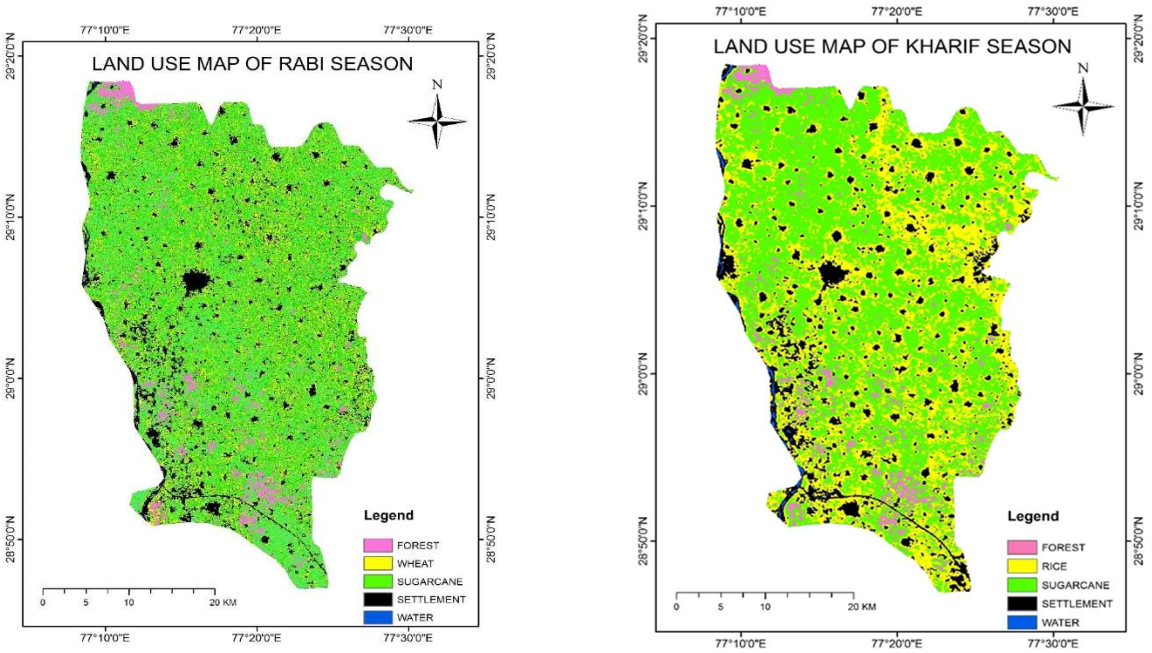
4. Results and Discussion

4.1 Crop discrimination

Each crop has a distinct spectral signature, therefore remotely sensed data can distinguish crops. Typical crop spectral reflectance displays pigment absorption in visible area (0.62-0.68 m) and significant near infrared reflection owing to leaf cellular structure. Red absorption and near-infrared reflectance indicate crop health (Navalgund et al., 1991b).

A rule-based classification analysis identified and distinguished rice, sugarcane, and wheat crops from other land use/land cover groupings. Rule-based feature selection using basic mathematical logics is successful. For crop discrimination, AWiFS temporal NDVI was utilized to create rules based on NDVI values of

various seasons, such as September. The transformation NDVI*127.5+127.5 linearized NDVI values between 0-255 (Ray S S et al., 2000).



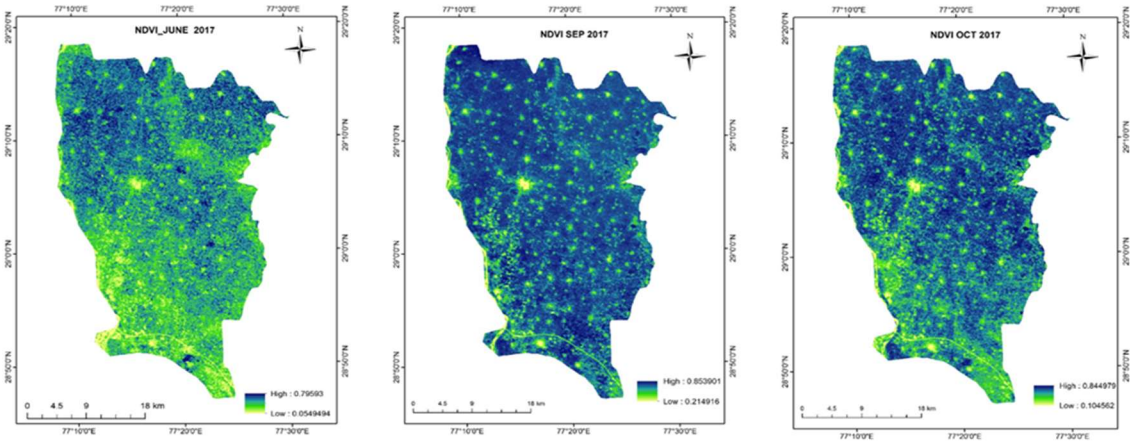


Fig 3. Shows the crop inventory map of Kharif Season & Rabi Season

4.2 NDVI Variation Throughout the Crop Season

A time-series of NDVI was created from all 9 AWiFS dates throughout crop growing seasons. Figure 4 show the 2017–2018 Kharif and Rabi NDVI temporal and geographical variance in the research region. NDVI peaks in November, whereas Rabi season (November–April) peaks in February. The greatest NDVI score indicates crop peak growth in Kharif and Rabi seasons. Kharif season had a higher average NDVI than Rabi season, perhaps owing to factors that accelerated crop growth: Higher rainfall (south-west monsoon), increased photosynthesis due to longer sunny hours, and wider crop area in Kharif season.

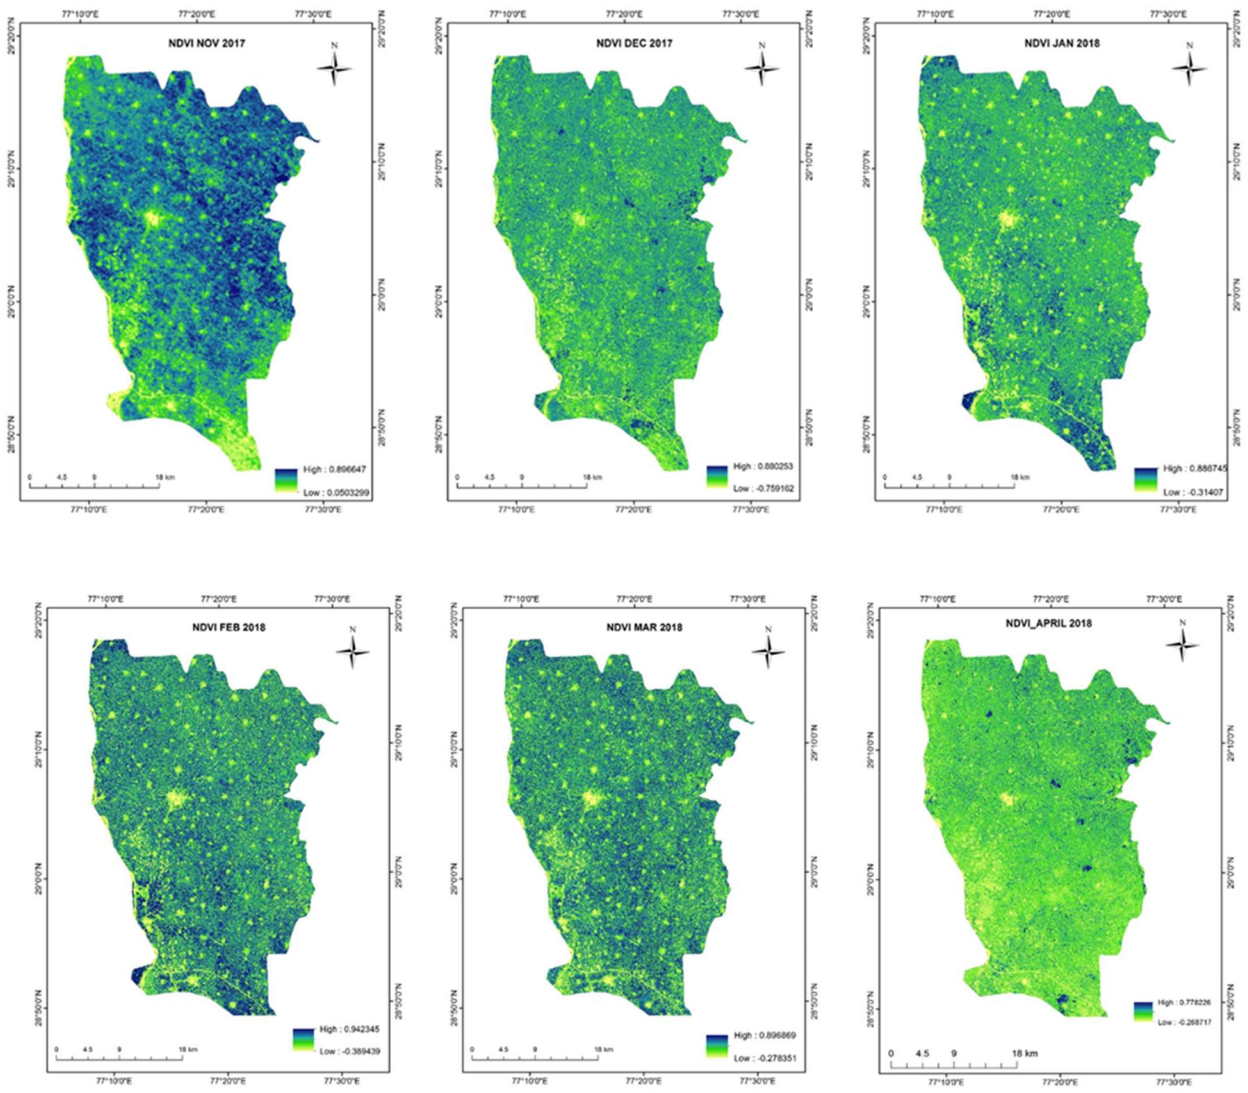

Fig 4. Spatial distribution of NDVI for June 2017 to April 2018

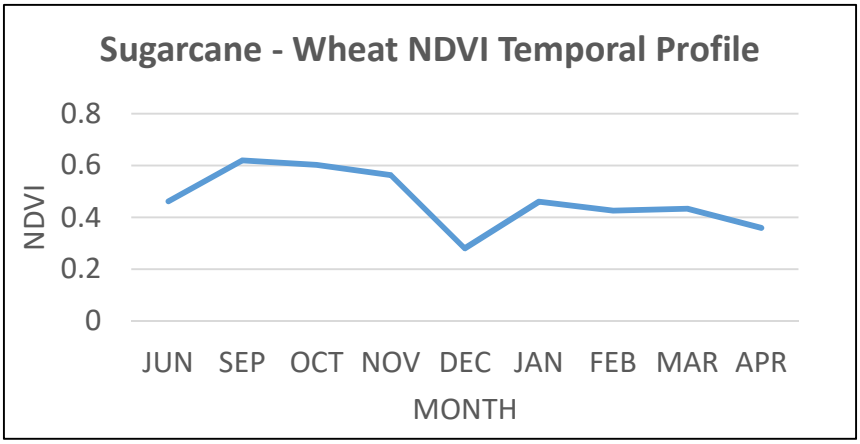

Fig 5. Temporal variation in NDVI for sugarcane–wheat cropping system

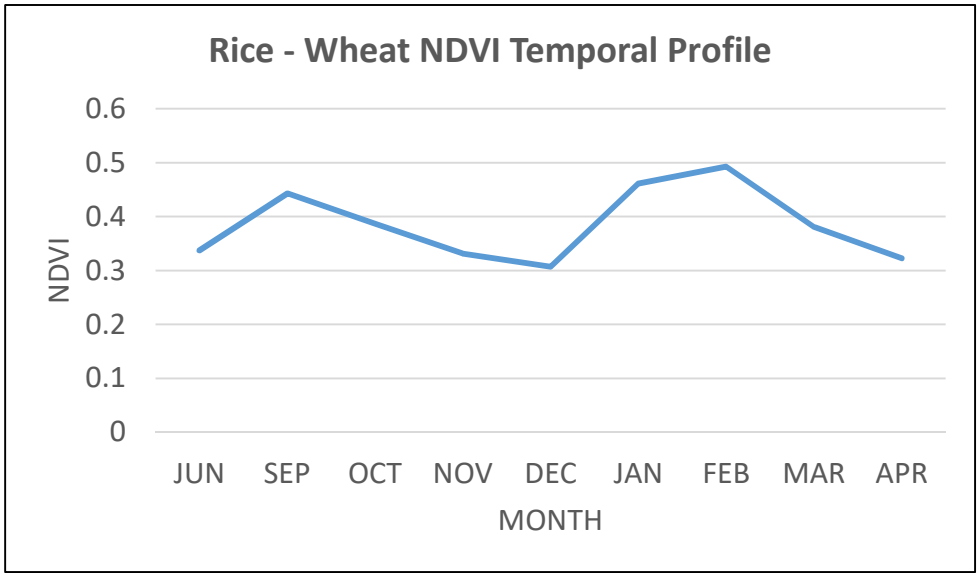

Fig 6. Temporal variation in NDVI for rice–wheat cropping system

The Normalized Difference Vegetation Index (NDVI) exhibited variability in relation to different crops and their phonological progression throughout the course of the growing season. The temporal fluctuations in NDVI for the sugarcane-wheat cropping system and the rice-wheat cropping system are shown in Figure 5 and 6, correspondingly. Figure 5.23 clearly demonstrates a decrease in NDVI values during December 2017. This decline corresponds to the development of wheat throughout the winter season after the harvest of sugarcane, as well as the early vegetative stage of sugarcane. The majority of the sugarcane crop was gathered in the month of December under the sugarcane-wheat agricultural system. Furthermore, a well-defined Normalized Difference Vegetation Index (NDVI) curve was found for the rice-wheat cropping system (refer to Figure 6). This curve clearly illustrates the trend of NDVI values while the rice and wheat crops undergo continuous phonological growth. These fundamental factors have effectively distinguished between the two systems. The observed NDVI patterns in this study exhibit similarities to the NDVI patterns reported by Kumari et al. (2013) in the context of sugarcane-wheat and rice-wheat cropping systems.

4.3 Basal Crop Coefficient

NDVI was used to derive the basal crop coefficient. The spatial representation of maps is below. Kcb and ETc fluctuated with crop and phenological development throughout the season, affecting crop water requirements. Fig.7 shows the temporal change of Kcb in Rice-Wheat and Sugarcane-Wheat cropping systems. Fig.7 show a fall in November and December 2017 owing to rice harvesting from Kharif season and a rise in Rabi season wheat transplanting. Rabi season adopts same profile. When temporal profile peaks, crop plant growth is maximum, hence water requirements are higher. The rice-wheat cropping system peaked in September and February with Kcb values of 1.2 and 1.23. In sugarcane-wheat cropping

system, Kcb temporal profile peaks in September and February with values of 1.24 and 1.03, although wheat peak value is low, perhaps because to mixed pixel combination with immature sugarcane plantings.

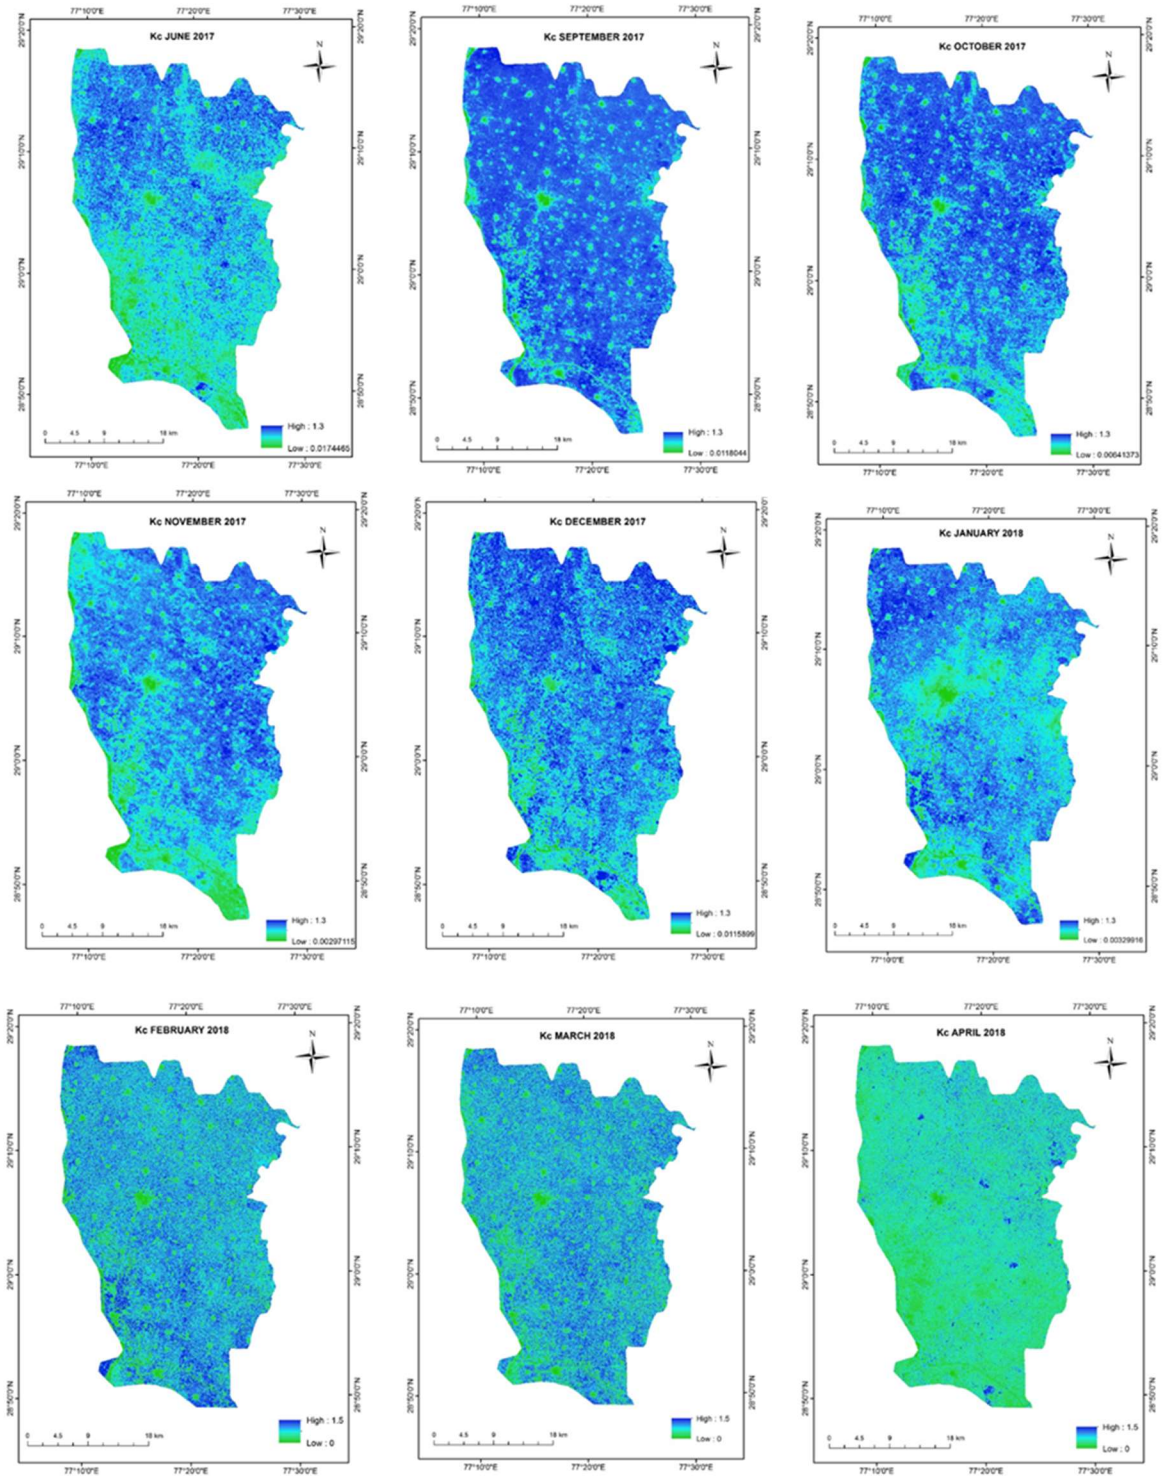

Fig 7. Spatial distribution of Kcb for June 2017 to April 2018

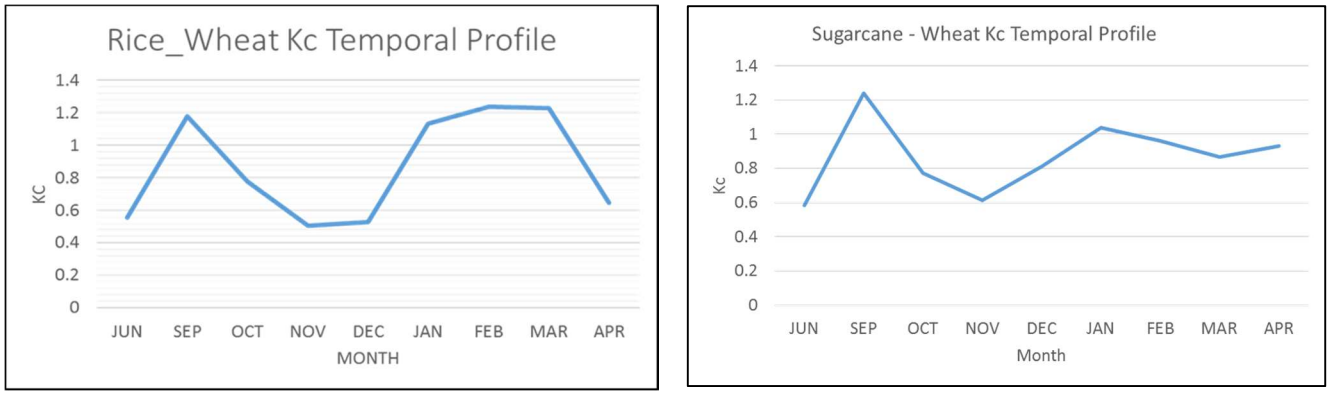

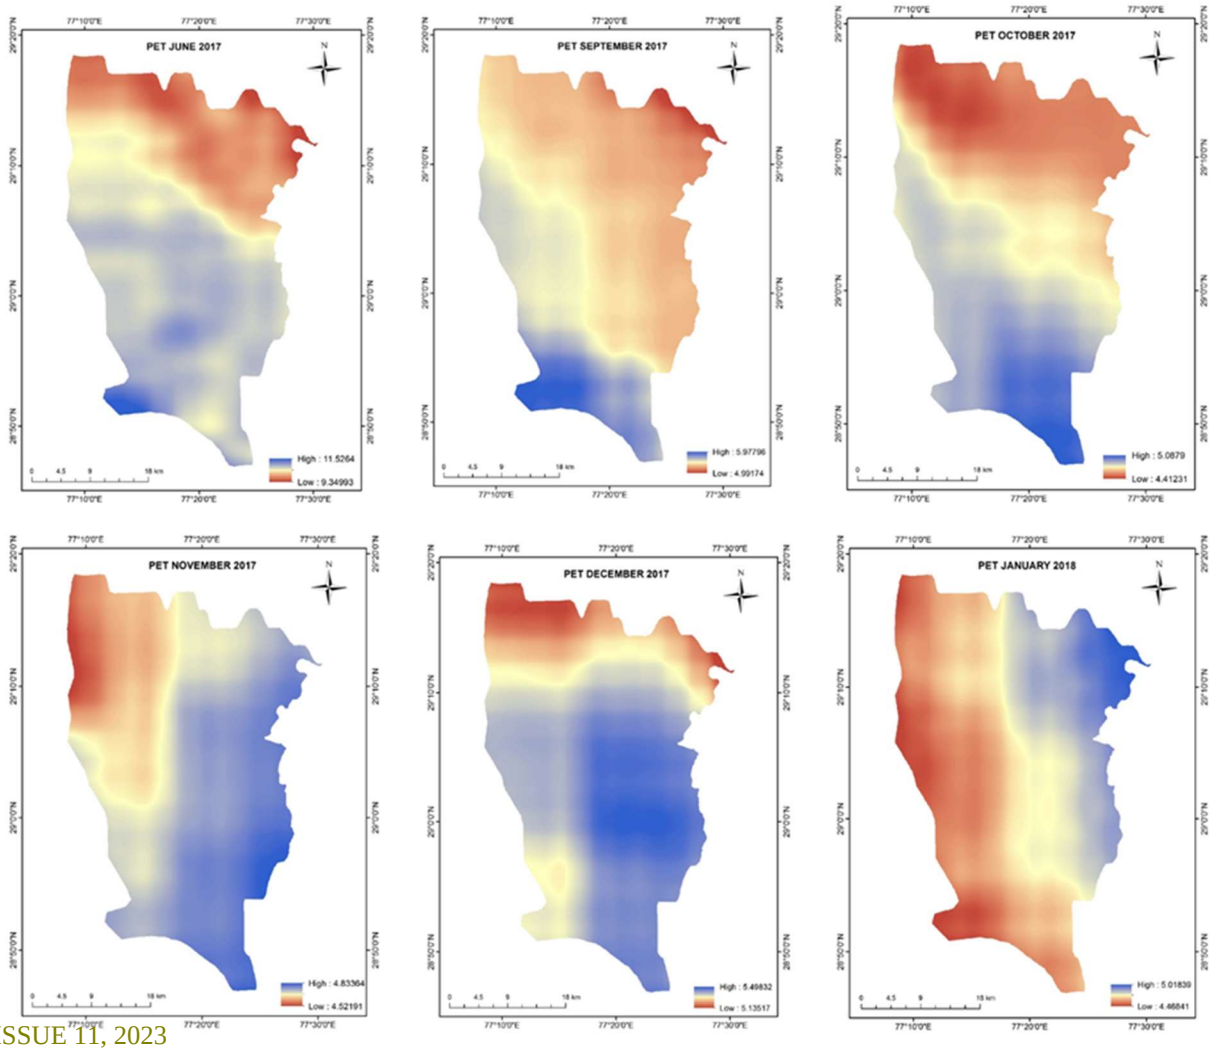

Fig 8 Temporal variation in Kcb for rice–wheat & sugarcane–wheat cropping system

4.4 Potential Evapotranpiration

The daily PET data downloaded from MOSDAC with a resolution of 5 km is resampled to 56 m resolution of AWiFS data. This is a daily average data product and the units of the PET data is in mm/day. The accuracy of the PET product is about 80-90% (INSAT-3D Manual, 2015). The temporal variation of daily PET as shown in figure 9. In Kharif and Rabi season the average value of PET in ranges between 4.41 to 5.91 mm/day and 3.30 to 5.42 mm/day

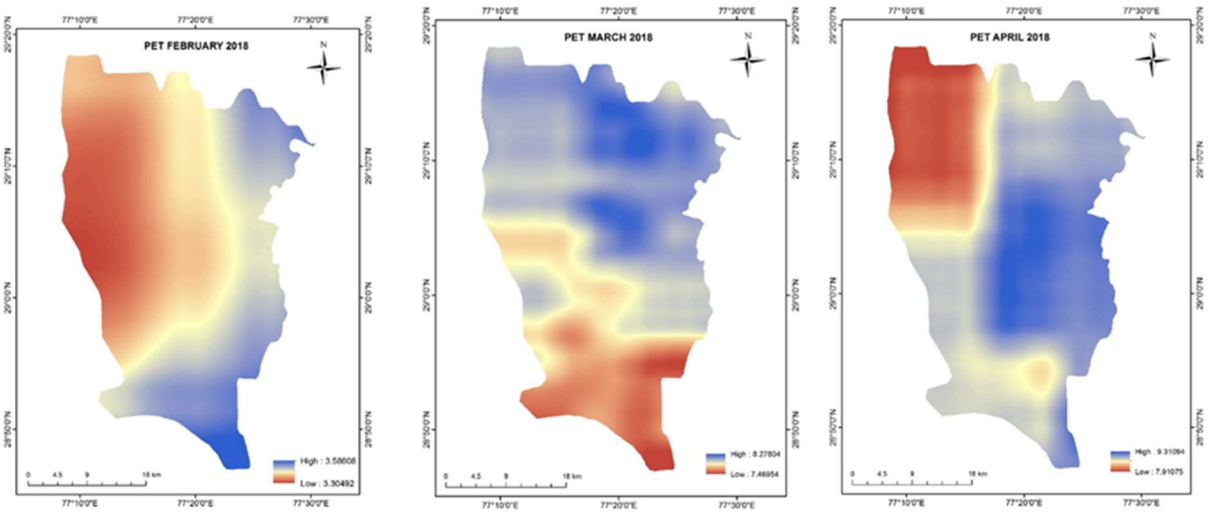

Fig. 9 Spatial distribution of PET (mm/day) for June 2017 to April 2018

4.5 Crop Evapotranspiration

The daily data from the PET (Potential Evapotranspiration) has been multiplied by the base crop coefficient (Kcb). The analysis of actual evapotranspiration (ET) based on the baseline crop coefficient and potential evapotranspiration (PET) reveals a marginal increase in ET during the month of November, followed by a fall in February. This may be attributed to the growth of sugarcane in November, with a significant portion being harvested by December. Lower readings are being recorded in February owing to the early vegetative development of wheat. The monthly photos exhibit a discernible pattern in the geographical distribution of monthly evapotranspiration. The evapotranspiration (ETc) exhibited a range of 3.09 to 6.87 mm day−1 throughout the period from June 2017 to April 2018. It is noteworthy that the mean ET value for sugarcane cultivation was determined to be 4.29 mm day−1. Sugarcane, a significant agricultural commodity in the nation, necessitates a substantial amount of water over its whole growth cycle, which typically spans 12 to 18 months. The specific duration may vary based on the agro-climatic areas, which range from sub-tropical to tropical. The crop's yearly water need in sub-tropical states like as Uttar Pradesh, Punjab, Haryana, and Bihar has been estimated to be 2000 mm (Shukla, S.K, 2017). The Food and Agriculture Organization (FAO) suggests that the range for this requirement falls between 1500-2500 mm. The estimated annual water demand for sugarcane in our research region is 2316.6 mm over a period of 18 months, and 1544.4 mm over a period of 12 months. The graphic shown below illustrates the spatial distribution of evapotranspiration (ET) and its temporal change.

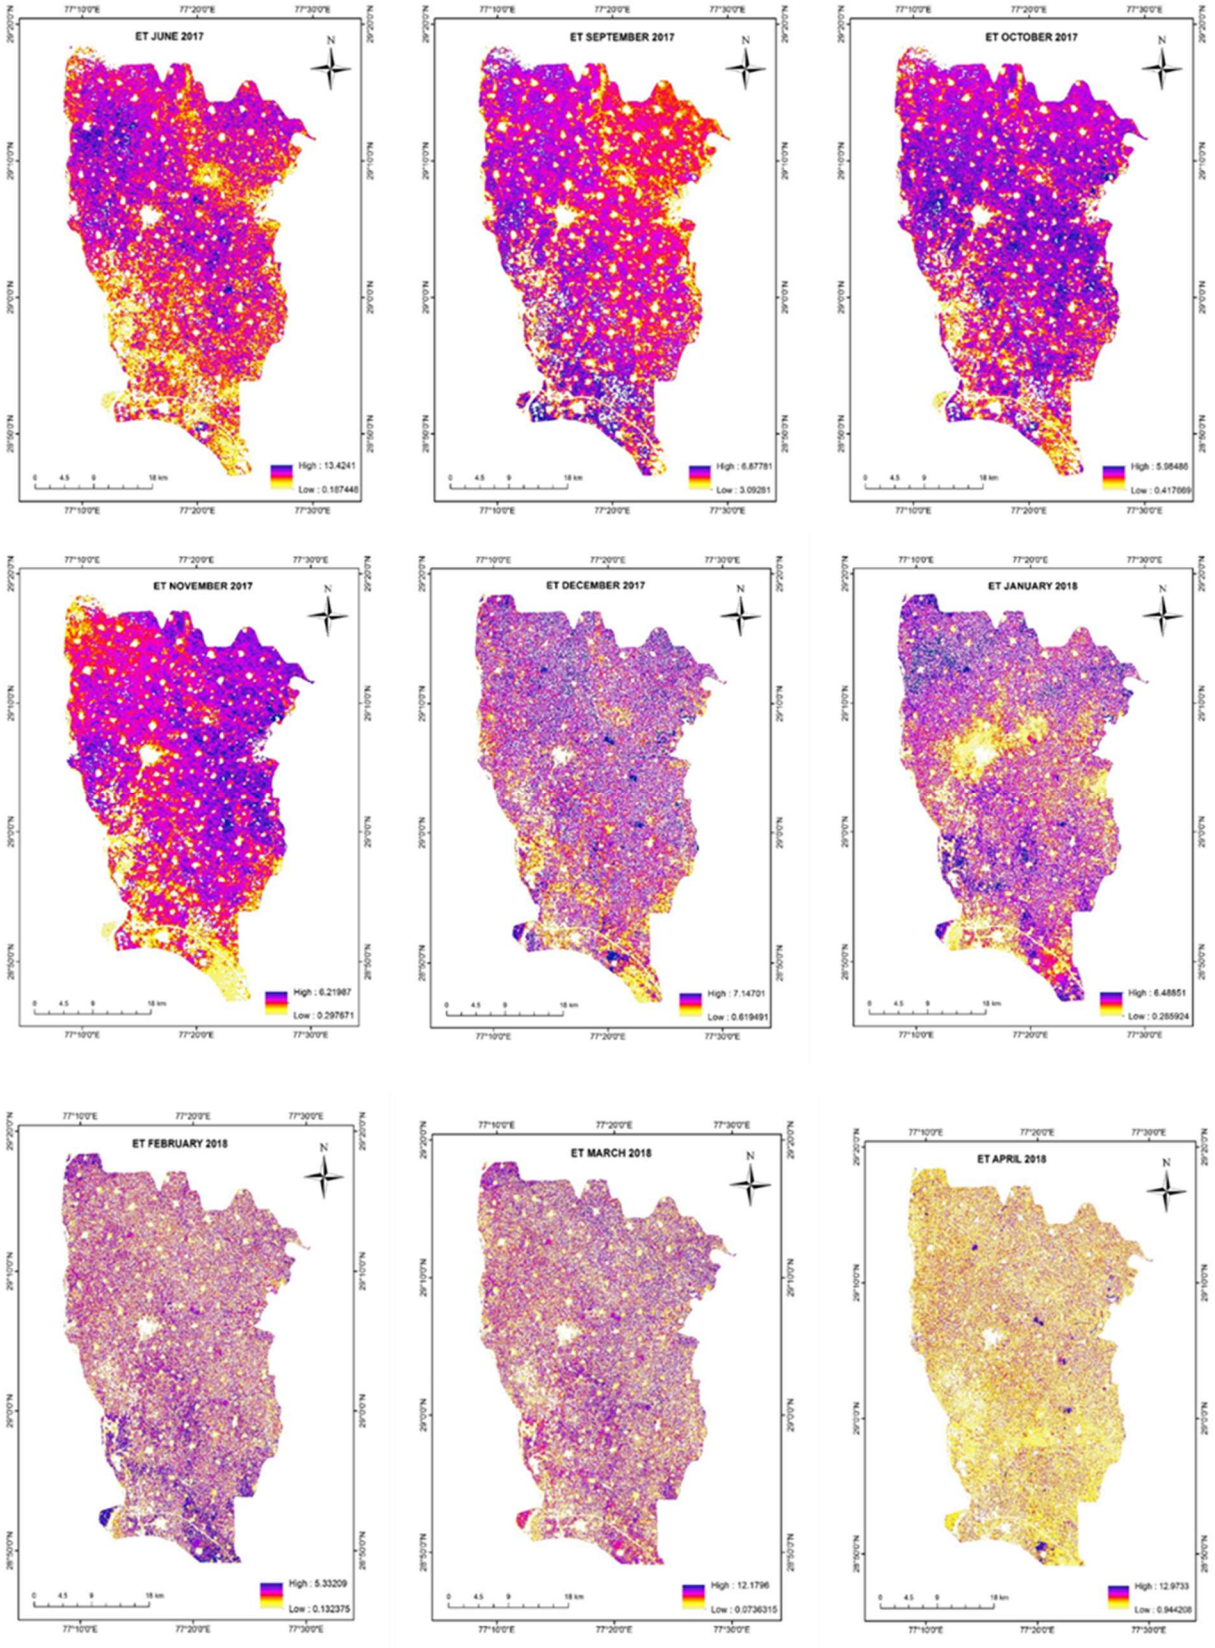

Fig. 10 Spatial distribution of Daily ET (mm/day) for June 2017 to April 2018

4.6 Land Surface Wetness Index (Lswi)

Land surface wetness index is a linear combination of NIR and SWIR bands. LSWI value ranges between -1 to +1 (Xiao et al., 2005).

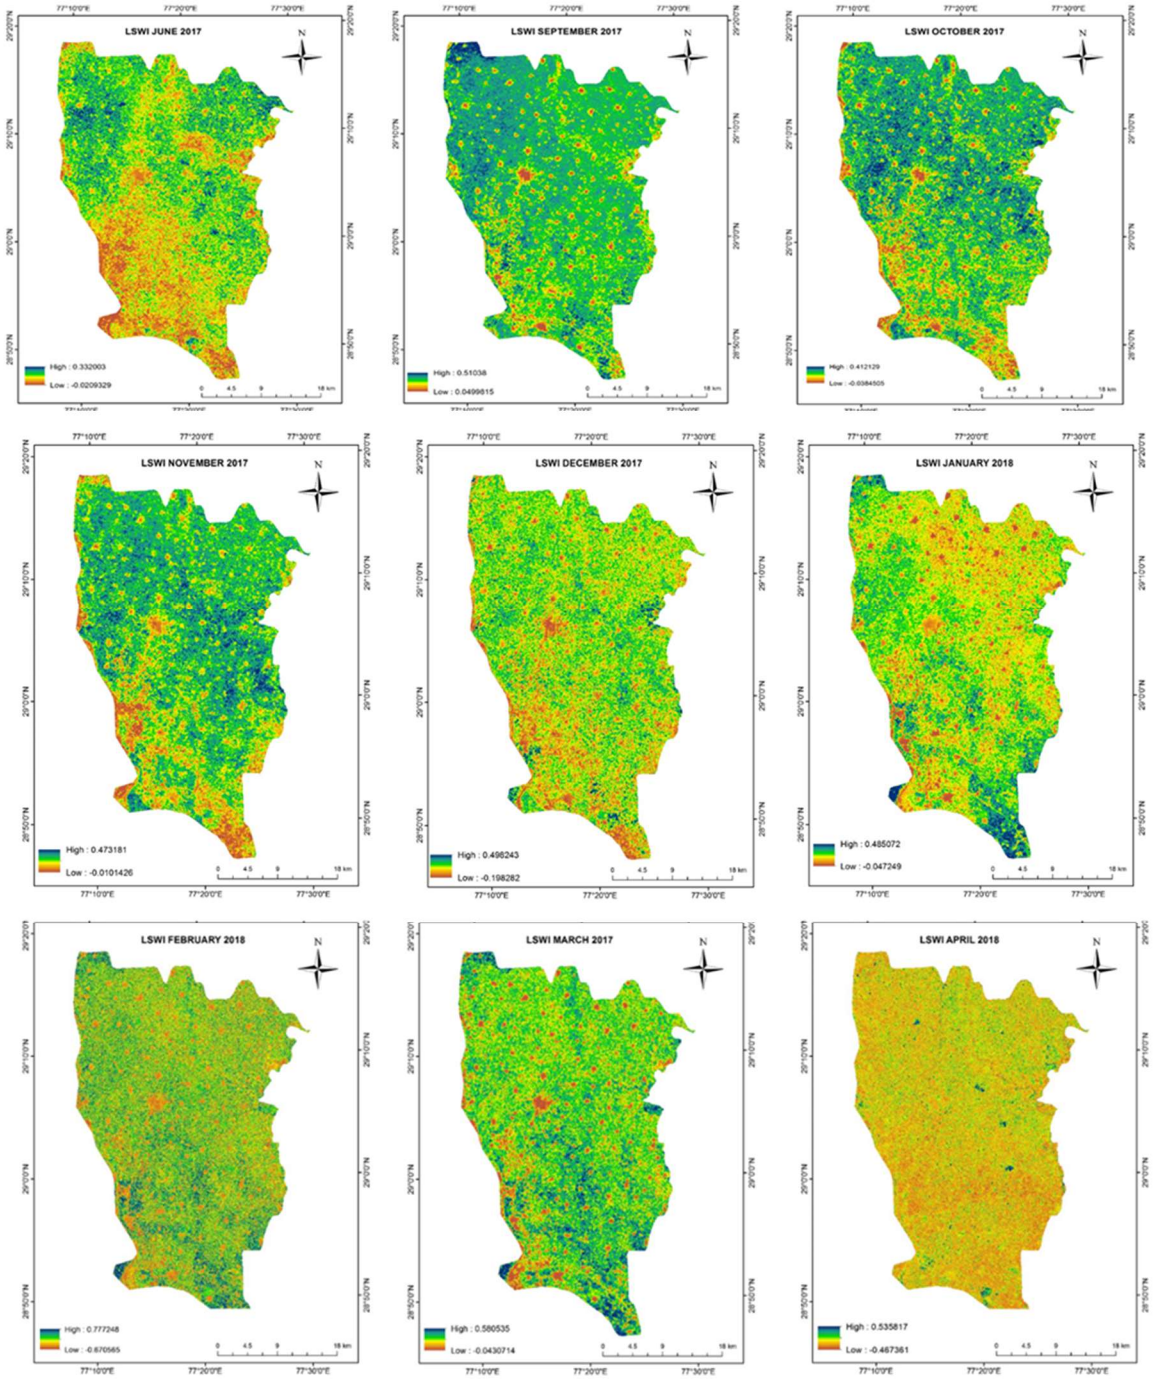

Fig. 11 Spatial distribution of LSWI for November 2017 to April 2018

4.7 Water Scalar Land Surface Wetness Index (Ws_Lswi)

The index is characterized by a numerical scale ranging from 0 to 1, with 0 denoting the absence of stress and 1 representing the presence of severe stress. The time distribution of water scalar may be noticed in Figure 5.71. Based on the findings from the period spanning June 2017 to January 2018, the observed trend may be attributed to the successive cultivation of kharif crops followed by rabi crops, leading to increased strain on the agricultural system. Subsequently, from February to April, the recorded values indicate a decline, which can be attributed to the commencement of crop harvesting during this period. In the month of June, a stress level of 0.56 was detected. However, in the subsequent months of September and October, the stress level exhibited a declining trend due to the increased vegetative development of sugarcane and rice crops. In November, there was a modest rise in the stress level, and by December, the value reached 0.50. This increase in stress may be attributed to the harvesting activities of rice and the presence of older sugarcane farms. The water scaler values show a decline subsequent to December, indicating a decrease in water stress. This trend aligns with the development of wheat crops occurring in January, February, and March. However, in April, a greater level of stress is noticed, as indicated by a value of 0.69, which may be attributed to the harvesting of wheat during this period.

CONCLUSIONS

The current work used a remote sensing-based technique to estimate crop evapotranspiration (ETc) from Bagpath, located in Western Uttar Pradesh. A rule-based classification using the Normalized Difference Vegetation Index (NDVI) was conducted to classify Kharif and Rabi Seasons. This included establishing thresholds for various classes within the research region. The resulting classification achieved an overall accuracy of 86.86% for Kharif crops and 79.72% for Rabi crops. The kappa coefficients for Kharif and Rabi crops were determined to be 0.81 and 0.712, respectively. The assessment of the NDVI profile effectively covers the growth season of the sugarcane-wheat and rice-wheat cropping system, allowing precise crop mapping within the designated research region. During the Kharif and Rabi seasons, the mean potential evapotranspiration (PET) varies from 4.41 to 5.91 mm/day and 3.30 to 5.42 mm/day, respectively. In the rice-wheat cropping system, a notable surge was seen between the months of September and February, with corresponding Kcb values of 1.2 and 1.23, respectively. The temporal profile of Kcb in the sugarcane-wheat cropping system exhibits peaks in the months of September and February, with corresponding values of 1.24 and 1.03, respectively. However, it is seen that the peak value of wheat is relatively lower, which might perhaps be attributed to the presence of mixed pixels resulting from the mixture of young sugarcane plants. The evapotranspiration (ETc) exhibited a range of 3.09 to 6.87 mm day−1 throughout the period spanning from June 2017 to April 2018. It is worth noting that the average ET value for sugarcane cultivation was determined to be 4.29 mm day−1. The estimated yearly water demand for sugarcane in our research region is 2316.6 mm over a period of 18 months and 1544.4 mm over a period of 12 months. The WS_LSWI data was collected between June 2017 and January 2018. In the month of June, a stress level of 0.56 was recorded. However, in the subsequent months of September and October, the stress level exhibited a downward trend due to the significant rise in vegetative development of sugarcane and rice crops. In November, there was a modest increase in stress levels, which may be attributed to certain factors. Finally, by December, the stress level reached a value of 0.50, likely due to the harvesting activities of rice and the presence of older sugarcane farms. The water scaler readings show a decline subsequent to the month of December, indicating a decrease in water stress. This decline coincides with the growing period of the wheat crop, which occurs mostly in the months of January, February, and March. However, in April, a greater level of water stress is detected, with a recorded value of 0.69. This increase in stress may be attributed to the harvesting of the wheat crop during this period.

Enhancing Urban Resilience: An Innovative Software Model for the Design and Administration of Gully Control Structures in Storm Water Systems

[1] Dr. V.Charan Kumar Reddy, [2] Paavan Kumar Reddy Gollapalli, [3] M. Reddi Bhaskara Reddy (Associate Professor)

[1&3] Department of Geography, Sri Venkateswara University, Tirupati, Andhra Pradesh India.
[2] Secretary, WG-SDTA, International Commission on Irrigation and Drainage

Abstract

Gully control structures are primarily used for the sake of soil and water conservation, as well as the development of plants. These structures are comprised of dams of many designs that are built with the intention of stabilizing the slope, storing water, and mitigating the speed of runoff. Software models refer to abstract representations or descriptions of software systems, which are used to facilitate understanding, analysis, and design of these systems. Various design options for permanent gully control structures are now available on the market. However, the focus of our work is on evaluating these options. An endeavor was initiated to build software that offers a simplified manner for the design of check dams. Permanent gully management structures are engineered interventions designed to mitigate the erosive effects of gullies in a long-lasting manner. The model was built with the Visual Studio 2013 software. The validation of GCS_Designer was observed in the check dam, resulting in an error of 2.7523%. The highest value for the lowest compressive stress was determined, with an associated error of 0.0681%. The minimum length requirement for the check dam. A total of 25 criteria are taken into consideration. The validation of GCS_Designer for check dam involves assessing the percentage of compliance with the 10 parameters. The error and remaining values indicate a zero % error. The aforementioned figures are subject to an overestimation of 80%. The positive value is seen, whereas the remaining numbers indicate an underestimation. The drop spillway has a length of 28.6 units. The percentage of values that are overestimated is greater than the percentage of values that are underestimated, with 71.4% of values falling into the latter category. In a similar vein, a mistake has been identified. The event took place at a drop inlet spillway, involving a total of eight parameters. It is worth noting that 87.5% of the values examined did not exhibit any errors. the present study, we aim to investigate the impact of social media on adolescent mental health. The design of chute spillways resulted in overestimation and underestimation of values, with 87.5% and 12.5% respectively. Please provide individual estimates for each item. Design considerations may be undertaken for the construction of a check dam, drop spillway, drop inlet spillway, and chute. The GCS_Designer program was used with great effectiveness to design a spillway that is adequate for the local circumstances.

1. Introduction

The issue of soil erosion in India exhibits significant variation in terms of extent, intensity, and characteristics throughout various regions of the nation. These variations are influenced by factors such as climate, terrain, soil composition, land use, and the prevailing agricultural economy. According to the research conducted by Dhruva and Ram in 1983, it was shown that soil erosion occurs at a rate of about 5334 metric tons per year, equivalent to 16.35 metric tons per hectare, alone as a result of agricultural and related activities.

The rivers of the nation transport around 2052 metric tons, equivalent to 6.26 tons per hectare. Approximately 29% of the total eroded soil, amounting to roughly 1572 million metric tons, is transported annually by rivers to the sea. Additionally, around 480 million metric tons of soil are deposited in different reservoirs, leading to a loss of storage capacity ranging from 1 to 2%. India has a total geographical area of 329 million hectares (Mha), with around 167 Mha (51% of the total) being impacted by significant water and wind erosion, as estimated by Das in 1985. Approximately 127 million hectares (Mha) of land are affected by significant soil erosion, while an additional 40 Mha have been degraded due to various factors such as gully formation, ravines, shift cropping, water logging, salinity, alkalinity, changing river courses, and desertification. According to Maji (2007), in India, about 120.72 million hectares of land, out of a total geographical area of 329 million hectares, are impacted by different types of land degradation. Among these, water-induced soil erosion above 10 megagrams per hectare per year accounts for 82.57 million hectares.

1.1 Control Measures for Gullies

Structures are primarily used for the purposes of soil and water conservation, as well as the development of plants. These structures are comprised of dams of different designs that are built with the intention of stabilizing the slope and decreasing the speed of runoff. Temporary and permanent structures may be used in situations where runoff is not severe and may be effectively managed via the presence of well-stabilized vegetation. The user's text is too short to be rewritten in an academic manner. Within gullies, the growth of vegetation is crucial until it becomes firmly entrenched. Temporary constructions are constructed using readily accessible materials found in the surrounding area, such as brush, poles, woven wire, loose gravel, and boards. In cases when runoff is substantial and the implementation of vegetation-based control measures is not viable, the use of permanent gully control structures becomes necessary. Several types of gully control structures include the check dam, drop spillway, drop inlet spillway, and chute spillway.

1.1.1 Check Dam

A check dam is a small-scale structure constructed across a watercourse to control the flow of water and prevent erosion. It is typically A check dam is a diminutive and transitory barrier positioned inside a ditch or watercourse with the intention of impeding erosion by diminishing the speed of fluid motion. The installation of a dam inside a ditch or channel disrupts the natural movement of water, resulting in a decrease in its velocity. While it is true that sedimentation may occur behind a dam, it is important to note that check dams are not primarily designed to catch sediment. Instead, they are often built using loosely distributed erosion stone or rip rap, or by using stone-filled gabions. The drop spillway, also known as a stepped spillway, is a hydraulic structure often used in dam engineering to safely release excess water from a reservoir.

The drop structure under consideration is classified as a weir structure, with a maximum allowable drop of 3 meters. The water passes through a hydraulic structure known as a weir, where it subsequently cascades over an apron, resulting in the dissipation of the water's energy. These structures are strategically positioned at regular intervals along a waterway, with the purpose of stabilizing it by altering its configuration from a consistently steep slope to a sequence of gradually sloping sections. Additionally, they serve as discharge points for tile and surface water located at the upstream terminations of drainage ditches. In the majority of soil conditions, it is feasible to construct drop spillways using commonly available masonry materials such as stone or brick, as well as concrete and concrete blocks, with or without reinforcing. The use of temporary storage to achieve a significant decrease in discharge along the structure is not appropriate.

1.1.3 Drop Inlet Spillway

The drop inlet spillway is a hydraulic structure often used in civil engineering projects to manage the flow of water. It is designed to efficiently divert excess water. A drop inlet or shaft spillway is characterized by the ingress of water by a horizontally oriented riser or inlet, often in the form of a circular or rectangular box. Subsequently, the water proceeds through a circular conduit, which may be either horizontal or nearly horizontal, towards an outlet protection system. The drop inlet spillway is a suitable solution for situations when it is necessary to regulate the flow of the downstream channel by creating a temporary storage area upstream of the structure. The structure comprises of a dam constructed from earthen materials and a spillway designed in the form of a pipe. The dam facilitates the temporary retention of runoff from the contributing watershed, while the spillway allows for the controlled release of the designed flow downstream. The adaptation occurs when the descent exceeds a magnitude of 3.0 meters. The drop inlet structure is comprised of three main components: the inlet, conduit, and outlet. When the form of the intake resembles a funnel, it is sometimes referred to as a Morning Glory or Glory Hole spillway.

1.1.4. The chute spillway

chute spillway is a hydraulic structure often used in dam engineering to safely discharge excess water from a reservoir. A chute spillway, also known as an open channel or trough spillway, is a hydraulic structure designed to transport the discharge of water from the upper portion of a channel or reservoir to the downstream channel level. This is achieved by using an open channel that is positioned next to a dam, abutment, or saddle. Chute structures are often used for the purpose of gully head management, proving to be effective for drops ranging from 5 to 6 meters in height. The chute spillway offers more advantages compared to the drop spillway in situations when there is a need to discharge a significant amount of runoff from a particular location. The flow in a chute spillway occurs at velocities that are classified as super-critical.

1.2 Design Planning

The design of structures necessitates thorough research into the numerous components that impact the characteristics of runoff approaching the structure. These investigations should include unique site circumstances, downstream flow characteristics, and any other special needs. There is a lack of universally applicable answers for the many challenges experienced in the field.

The design should include a comprehensive review of all the pertinent aspects that exert influence on the task. The data necessary for the design of these structures is as follows.

1. The topographic map of the contributing watershed and the adjacent downstream region is being referred to.

2. Soil data refers to information pertaining to the composition, properties, and characteristics of the soil within a certain area or region.

3. Rainfall data and characteristics include the quantitative measurements and qualitative attributes associated with precipitation, including its frequency, intensity, duration, and spatial distribution.

4. The existing land use pattern denotes the current arrangement and use of land within a specific geographic area, including various activities such as agriculture, residential, commercial, industrial, and natural areas.

1.3 Study Scope

The primary objective of a watershed development program is to mitigate the adverse effects of water and soil by enhancing the process of infiltration into the soil. This is achieved via the implementation of measures to regulate and mitigate excessive runoff, effectively manage and harness runoff, and minimize soil erosion in order to safeguard the integrity of the land. The successful design of buildings that are both economically efficient and safe requires a comprehensive understanding of the subject matter, proficiency in engineering principles, and much practical experience in the area. It is important to consider the local design factors, which include the soil texture, rainfall patterns, and agricultural practices of the indigenous population. A significant number of individuals engaged in watershed management lack enough proficiency in design, while existing textbooks on soil and water conservation fail to provide comprehensive design guidance tailored to specific regional contexts. Hence, it is important to develop a complete software solution for the purpose of managing soil and water conservation structures. There are other software models that exist for the creation of permanent gully control systems. However, the focus of our work was to produce software that is characterized by its simplicity.

The method for the design of check dams and permanent gully control systems. The model was constructed with Visual Studio 2013. The model was developed with the purpose of serving as a dam designer for field workers, while also functioning as an instructional tool for students to analyze the impact of modifying input parameters on the design output.

Taking into consideration the aforementioned concerns, the current investigation was conducted with the accompanying aims. The objective is to **1. create software that may be used for the purpose of designing gully control structures. 2. A Comparative Analysis of Various Parameters between Software-generated Output and Manually-generated Output. 3. The statistical analysis is used to compute the error for various parameters of structures.**

2. MATERIAL AND METHODS

Process for Gully Control Structure Design The gully control structure design process has three phases: hydrologic design, which calculates runoff rates and volumes. intended to manage, hydraulic design examines dimensions' needs. structure to withstand high runoff via drop and chute structures and structural design provide components strength and stability. Structural components. It analyses structure-affecting forces.

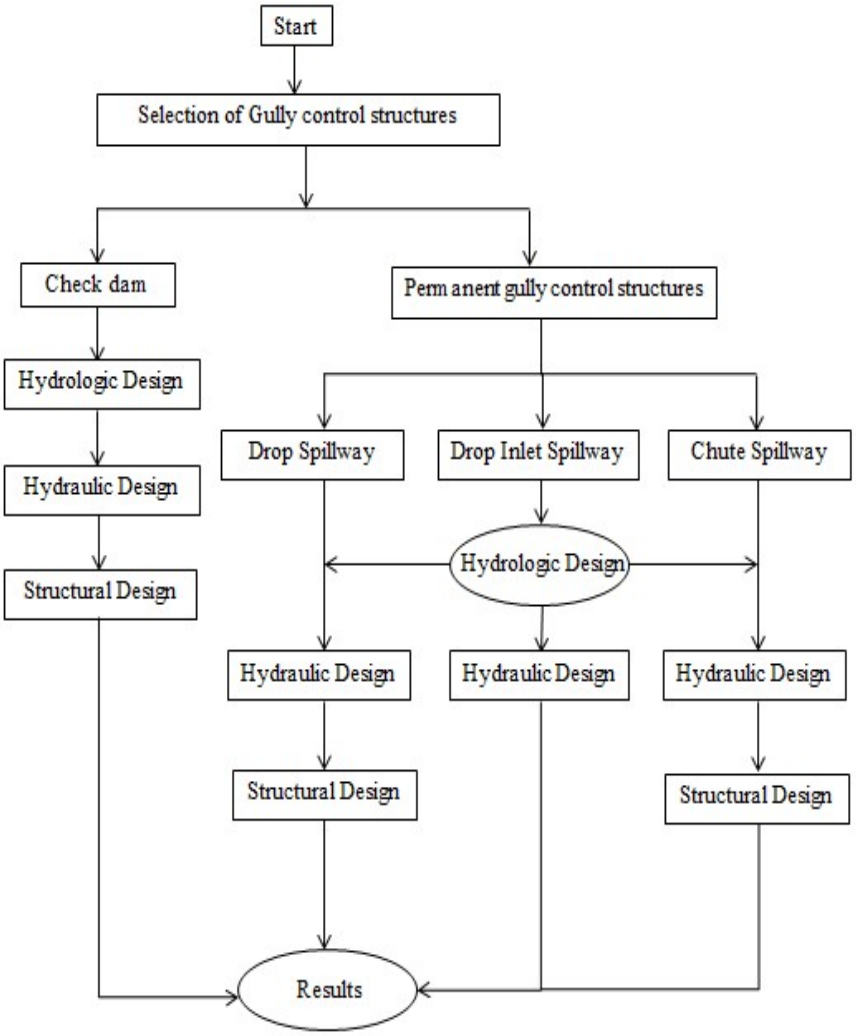

Fig.2.1 Flow chart for software design of gully control structures

2.2 DESIGN PROCEDURE OF CHECK DAM

2.2.1 Hydrologic Design

Structure can be designed for the maximum possible peak runoff rate which may occur within a reasonable frequency of interval (25/30/50 Years).The peak rate of runoff for a catchment is generally estimated for check dam by Dicken's Method.(WALAMTARI)

Computation of maximum flood discharge $\boldsymbol{Q = CA^{3/4}}$, cusecs

Where, **Q** = Maximum flood discharge (Cusecs)

C = Dickens constant (Appendix-I)

A = Catchment Area (square miles)

2.2.2 Hydraulic Design

The step by step procedure of check dam hydraulic design for software development by using the visual basic as described below.(Dhan Foundation, Chittoor)

I. CREST LEVEL OF THE CHECK DAM ($\mathbf{l_C}$)

The apex of the weir body wall where water is at full reservoir level is its crest.

II. HEIGHT OF THE CHECK DAM($\mathbf{H_b}$)

It is the elevation difference between the highest point and lowest point of water flow in the watershed.

III. LENGTH OF CHECK DAM, $\boldsymbol{L = 4.75\sqrt{Q}}$, m

IV. DISCHARGE PER METER RUN, $\boldsymbol{q = \frac{Q}{L}}$, Cumecs

V. APRON LEVEL, $\mathbf{l_A = [\, l_c - H_b]}$, m

VI. TOP LEVEL OF DOWNSTREAM(D/S) SOLID APRON, $\mathbf{l_{DA} = l_A}$, m

VII. DOWNSTREAM TAIL WATER LEVEL (T W L)

Tail water depth, $\mathbf{d_t = [\frac{Q}{1.656L}]^{2/3}}$, m

T W L on D/S, $\mathbf{l_{TW} = l_{DA} + d_t}$, m

VIII. UPSTREAM MAXIMUM FLOOD LEVEL

The depth of water flowing over the crest of the Check Dam is the difference between the Maximum Water Level and Full Reservoir Level.

- Head over crest

$$\mathbf{d_c=[\frac{Q}{1.845L}]^{2/3}}, \text{ m}$$

- Maximum flood level on U/S

$$\mathbf{l_{FU} = l_c + d_c}, \text{ m}$$

Provide 0.3 m thickness of foundation wall below the bottom level of check dam

IX. SCOUR DEPTH CALCULATIONS

- Regime Scour depth **R = 1.346 $[\frac{q^2}{f}]^{1/3}$,** m

  f = Laceys silt factor (Appendix-II)

- D/S bottom level of foundation = **[l_{TW} - 1.5R],** m

  Provide D/S cut-off wall 1.5 m below the body wall of check dam

  - U/S bottom level of foundation = **[(l_{FU}) - R],** m
  - Provide U/S cut-off wall 0.9 m below the foundation bottom level

X. LENGTH OF APRONS , L_A = **$10C_a [(H_b * q)/231]^{0.5}$**, m

XI. LENGTH OF SOLID APRON **(L_{SA})**

L_1= [1.5 + 2*(dc* h)$^{0.5}$], m

Where,**h = [(l_{FU}) - (l_{TW})],** m

L_2= [2*(H_b + d_c)], m

L_3= [4*C_a *(H_b/33)$^{0.5}$], m

L_{SA}= [(L_1+L_2+L_3)/3], m

XII. LENGTH OF TALUS, **L_T = L_A- L_{SA},** m

Provide length of talus at least 2 m

XIII. THICKNESS OF SOLID APRON, **t_{SA} = [0.5 * (d_c + h)$^{0.5}$],** m

Provide solid apron for a thickness of (t_{SA} – 0.1) m with 0.1 m thick wearing coat over it.

2.2.3 Structural Design

The following components are designed to develop software for the structural stability of the structure as given below. (Dhan Foundation, Chittoor)

I. BODY WALL OF THE CHECK DAM

- Top width of the check dam, **Tw = [(3*d_c)/(2*spwc)],** m

  Note: Provide 0.6 m top width if calculated T_W is less than 0.5 m

- Bottom width of the check dam, **Bw = [(H_b + d_c)/(spwc)$^{0.5}$],** m

  Note: Provide B_W as equal to H_b, if calculated B_W is less than H_b

II. THICKNESS OF CUSHION WALL

Solid wall constructed at the downstream end of apron, **t_c = (Tw/2),**m

III. STABILITY CALCULATIONS OF WALL

Stability of the wall can be calculated in two cases namely consider water is up to the crest level and water is discharging at maximum flood level.

Case I: Consider water is up to the crest level

For Calculating stability of wall formulas are considered as shown in the Table3.1

Table: 2.1 Inflow water is up to crest level

Force (1)	Magnitude (t/m) (2)	Lever arm (m) (3)	Moments about A(t) (2)*(3)
W_1	T_W*H_b*spwc	$(T_w/2)$	
W_2	$0.5*(B_w - T_w)*H_b*spwc$	$\{[(B_w - T_w)/3]+T_w\}$	
W_H	$[H_b]^3/6$	-	
Total	$\sum W =$		$\sum M =$

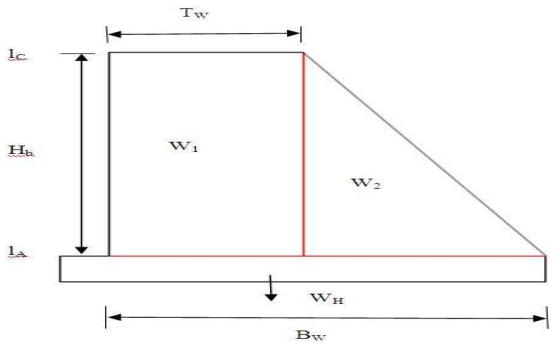

Fig.2.2 Water is up to crest level of the check dam

- Resultant $R_{s1} = \sum M/\sum W$, m

a) Check against tension

The resultant thrust lies in the middle third of the base width {**i.e.** $(B_w/3)$ **to** $[(2*B_w)/3]$m,then the wall is safe against tension at its base.

b) Check against overturning

The resultant thrust is passing within the base then the wall is safe against overturning.

c) Check against compression

- Eccentricity developed $(e) = [(0.5*B_w) - R_{s1}]$, m
- Eccentricity limit $= \{B_w/6\}$, m
- Compressive stress developed

*Maximum compressive stress $=\{(\sum W/B_w)*[1 + \{(6*e)/B_w\}]\}$ t/m^2

*Minimum compressive stress $=\{(\sum W/B_w)*[1 - \{(6*e)/B_w\}]\}$ t/m^2

The stresses developed are within permissible limits then it is safe against compression.

Case II: Water is discharging at maximum flood level

For Calculating Discharge at maximum flood level formulas are considered as shown in the Table 3.2

Table: 2.2 Water is discharging at Maximum flood level (M F L)

Force (1)	Magnitude(t/m) (2)	Lever arm (m) (3)	Moments about A (t) (2)*(3)
W_1	T_W*H_b*spwc	$(T_w/2)$	
W_2	$0.5*(B_w - T_w)*H_b*spwc$	$\{ [(B_w - T_w)/3]+T_w \}$	
W_3	T_w*d_c*spww	$(T_w/2)$	
W_4	$0.5*[(d_t/H_b)*(B_w - T_w)]*d_c*spww$	$\{ [\{(d_t/H_b)* (B_w - T_w)\}/3]+T_w \}$	
W_5	$[(d_t/H_b)*(B_w - T_w)]*(l_c - l_{TW})*spww$	$\{ [(B_w - T_w)/2]+T_w \}$	
W_6	$0.5*[(d_t/H_b)*(B_w - T_w)]*d_t*spww$	$\{ (B_w)- [(d_t/H_b)* (B_w - T_w)] \}$	
W_H	$[H_b]^3/6$	-	
Total	$\sum W =$		$\sum M =$

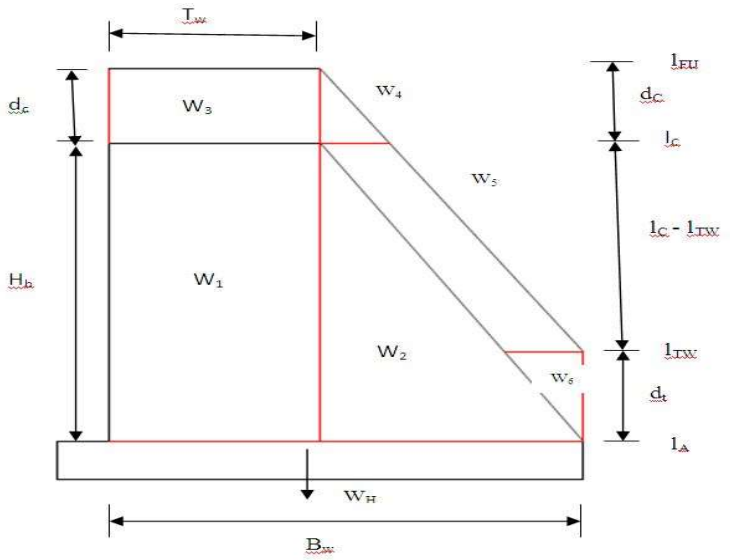

Fig.2.3 Check dam is discharging at maximum flood level

- Resultant $\mathbf{R_{s2}} = \sum \mathbf{M}/\sum \mathbf{W}$, m

a) <u>Check against tension</u>

The resultant thrust lies in the middle third of the base width **{i.e, $(B_w/3)$ to $[(2*B_w)/3]$**m,then the wall is safe against tension at its base.

b) Check against overturning

The resultant thrust is passing within the base then the wall is safe against overturning.

c) Check against compression

- Eccentricity developed **(e) = [(0.5*B_w) – R_{s1}]**, m
- Eccentricity limit = **{B_w/6 },** m
- Compressive stress developed

*Maximum compressive stress=**{ (∑W/B_w)*[1 + {(6*e)/B_w}] }** t/m^2

*Minimum compressive stress=**{ (∑W/B_w)*[1 - {(6*e)/B_w}] }** t/m^2

The stresses developed are within permissible limits then it is safe against compression.

IV. CREEP LENGTH PROVIDED FOR CHECK DAM

- Creep Length required, **C_L = ($C_a$$H_b$),** m
- Creep length provided, **C_{LP} =L_h + L_v** , m

= [2T_W+B_W+L_A+L_T] + [0.3+0.9+t_{SA}+H_b]

If Creep length provided is more than the creep length required hence design is safe against creep otherwise Provide “creep length required”

V. CHECK AGAINST PIPING

- Weighted creep ratio (C_W) = {[∑L_h + 2∑L_v]/(3H_b)}

The calculated C_w is greater than tabulated C_w value (Appendix-III) then the structure is safe against piping.

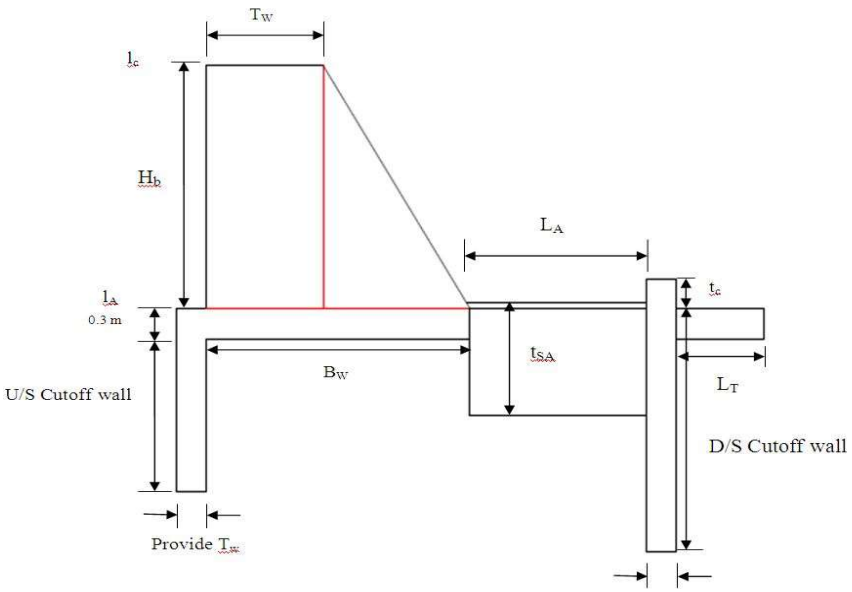

Fig.2.4 Creep path provided for check dam

2.3 DESIGN PROCEDURE OF DROP SPILLWAY

2.3.1 Hydrologic Design

Flood discharge volume calculated by computing the runoff rate for 25/ 30/ 50 years return period. Runoff rate is calculated by Rational method. (Ghanshyam Das, 2012)

Computed discharge value, **Q=CIA/360**

Where, Q= peak runoff rate, cumecs

C= coefficient of runoff (Appendix-IV)

= **(1/A)*(C_1A_1+ C_2A_2+ C_3A_3+……..+ C_nA_n)**

I= Intensity of rainfall, mm/h

2.3.2 Hydraulic Design

The width of gully and depth of gully are known then determining the length of crest, depth of the weir to provide required capacity and maintain free board. (Ghanshyam Das, 2012)

I. LENGTH OF WEIR CREST, **L=Width of gully – 0.5,** m

II. HEIGHT OF WATER AT CREST, **$Q=(2/3)* C_d *(2g)^{1/2}*L*h^{3/2}$,** cumecs

Where C_d = discharge coefficient (0.6)

g = 9.8, m/sec^2

L = length of weir crest, m

h = height of water at crest, m

III. HEIGHT OF THE WEIR, **d = h+0.15**, m

IV. HEIGHT OF WATER DROP FROM THE CREST, **H=depth of gully –d,** m

V. BASIN/APRON LENGTH, $\mathbf{L_B = 0.75(H+d)+H,}$ m

VI. WIDTH OF THE SIDE WALL, **W=H+d+1,** m

VII. HEIGHT OF THE SIDE WALL

a) At the end sill end = at least 1.5d $\geq$H/2, m

b) At the weir end = equal to gully width, m

VIII. LENGTH OF THE WING WALL, $\mathbf{L_W = 2.25h}$, m

IX. DEPTH OF THE TOE WALL, **h +0.1**, m

2.3.3 STRUCTURAL DESIGN

The force analysis of drop spillway can be carried out here. (Ghanshyam Das, 2012)

I. TOTAL UPLIFT PRESSURE, $\mathbf{P_U = H-0.5,}$ m

II. ANALYSIS OF FORCES

Drop spillway structural forces can be calculated, if know the volume of component, material density, lower arm length of the structure as described in the Table 3.2.

Table: 2.3 Analysis of forces of the Drop Structure

Forces on structure	Volume of component per unit length (m^3)	Material density (kg/m^3)	Force per unit length of structure (kg/m) (2)*(3)	Lower arm length (m)	Moment(kg) (4)*(5)	Type of moment
(1)	(2)	(3)	(4)	(5)	(6)	(7)
P_1	(d*H)*1			0.5*H		Over Turning
P_2	$0.5*H^2*1$			(1/3)*H		Over Turning
P_{u1}	$0.5*(L_B+1.5)*1*1$			$(2/3)*(L_B+1.5)$		Over Turning
P_{u2}	$0.5*(L_B+1.5)*1$			$0.5*(L_B+1.5)$		Over Turning
W_1	(H-0.5)*1*1			$((L_B+1.5)-0.5)$		Restoring
W_2	0.5*(H-0.5)*0.5			$L_B+[(2/3)*0.5]$		Restoring
W_3	$0.5*(L_B+1.5)*1$			$0.5*(L_B+1.5)$		Restoring

1- Safety against overturning

Safety against overturning is calculated by following formula

Total restoring moment > Total overturning moment

2- Safety against sliding

For safety against sliding,

$\sum f_h$ should not be greater than $C_f*\sum f_h+C_rA$ i.e. **[$\sum f_h < (C_f*\sum f_v+C_rA)$]**

Where, $\sum f_h = P_1+P_2$ = horizontal forces, m^3

$\sum f_v = W_1+W_2+W_3 - P_{u1} - P_{u2}$ = vertical forces, m^3

$C_f = \tan\emptyset$, ($\emptyset$ = angle of internal friction of soil)

C_r = cohesion resistance of soil (Kg/m^2)

$A = [H*(L_B+1.5)]$=area of plane of sliding , m^2

If it satisfies $\sum f_h < (C_f*\sum f_v+C_rA)$ sliding is safe otherwise redesign

3- Safety against tension

The eccentricity (e) should not be greater than [width (d)/6] then the structure is safe against tension.

$e = Z-[Width(d)/2]$, m

$Z=[\sum moments/(\sum f_v)]$, m

4-Safety against compression

The force should be compressive in nature, so that there is no floatation of the structure. Thus, the resultant force should act downwards,

$$\text{Contact pressure, } P_e = \{(\sum f_v/A)*[1\pm(6e/d)]\}$$

Where the +ve sign will give pressure at the upstream, and the –ve sign will give pressure at the downstream.

5- Safety against piping

The weighted creep ratio (C_W) should be higher than the recommended value then the structure is safe against piping.

$$C_W = \{(\sum L_h+2\sum L_V)/(3H)\}$$

Where, C_W = Weighted creep ratio

$\sum L_h$ = Sum of all horizontal (flat) contact distances, m

$\sum L_V$ = Sum of all vertical r steep contact distances, m

H = Head between the head water and the tail water, m

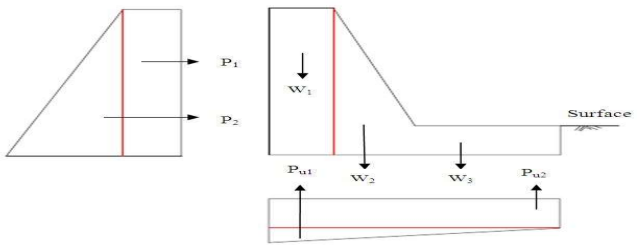

Fig.2.5 Analysis of forces for Drop spillway

2.4 DESIGN PROCEDURE FOR DROP INLET SPILLWAY

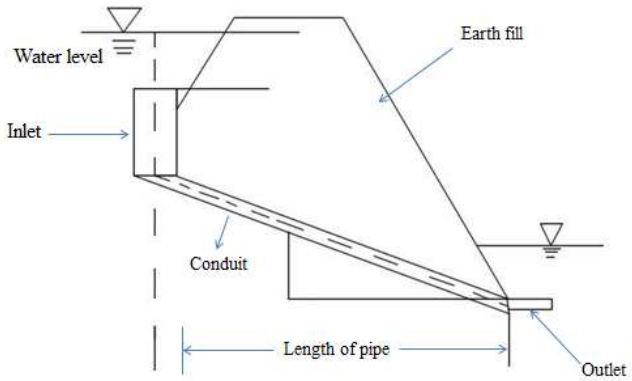

Fig.2.6 Components of Drop inlet spillway

2.4.1 Hydrologic Design of drop inlet spillway

Estimation of flood discharge volume by computing the Runoff rate for 25/ 30/ 50 years return period. Runoff rate is calculated by Rational method.(Ghanshyam Das, 2012)

Computed discharge value, **Q=CIA/360** , cumecs

Where, Q= peak runoff rate, cumecs

C= coefficient of runoff (Appendix-IV)

$= \mathbf{(1/A)*(C_1A_1+ C_2A_2+ C_3A_3+\ldots\ldots\ldots..+ C_nA_n)}$

I= Intensity of rainfall, mm/h

2.4.2 Hydraulic Design for drop inlet spillway

The width of gully and depth of gully are known, the design consists of determining the length of the pipe, velocity of flow, radius of pipe, natural slope. (Ghanshyam Das, 2012)

I. LENGTH OF PIPE,**L**=Base width of the embankment, m

II. VELOCITY OF FLOW IN CULVERT PIPE, $\mathbf{V= (2gH)^{0.5}/(1+K_e+K_cl)^{0.5}}$, m/s

Where, K_e = Coefficient of entrance losses

K_c = Head loss coefficient

g = 9.81, m/s^2

H= water head, m

III. CROSS SECTIONAL AREA OF A PIPE, $\mathbf{A=Q_0/V}$, m^2

Where, Q_0=discharge, cumecs

IV. RADIUS OF A PIPE, $\mathbf{r = (A/\pi)^{0.5}}$, m

V. DIAMETER OF THE PIPE, **d = 2 * r,** m

VI. NATURAL SLOPE, $\mathbf{S_n= (K_cV^2/2g) /(1-(K_cV^2/2g)^2)^{0.5}}$, **%**

VII. PIPE SLOPE=**height of drop/pipe length,%**

2.5 DESIGN PROCEDURE OF CHUTE SPILLWAY

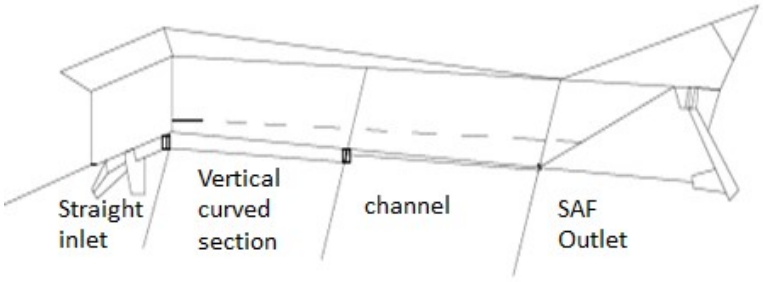

Fig.2.7 Chute spillway

2.5.1 Hydrologic Design of chute spillway

Estimation of flood discharge volume is calculated by computing the runoff rate for 25/ 30/ 50 years return period. Runoff rate is calculated by Rational method. (Ghanshyam Das, 2012)

Computed discharge value,**$Q=CIA/360$**

Where, Q = peak runoff rate, cumecs

C= coefficient of runoff (Appendix-IV)

= **$(1/A)*(C_1A_1+ C_2A_2+ C_3A_3+\ldots\ldots\ldots..+ C_nA_n)$**

I= Intensity of rainfall, mm/h

2.5.2 Hydraulic Design of chute spillway

The design consists of determining the length of weir, head loss, sequent depth, if know the width and depth of gully. (Ghanshyam Das, 2012)

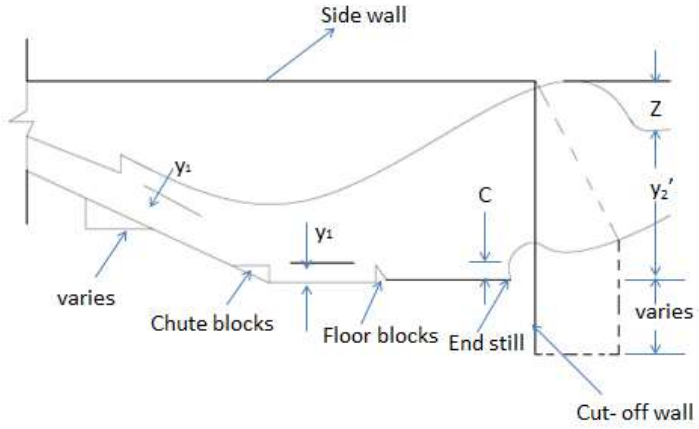

Fig.2.8 Sectional view of chute spillway

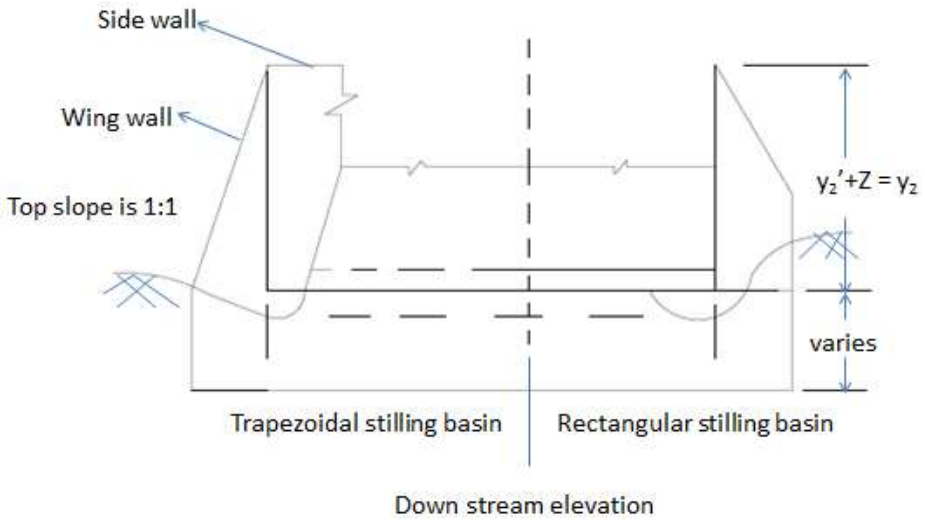

Fig.2.9 SAF stilling basin outlet

I. LENGTH OF STRAIGHT INLET , **$L=Q/1.77*H^{3/}2$,**m

Q=Discharge, cumecs

H=Depth of flow, m

II. HEAD LOSS AT TOE, **h_e=drop in gully head(D)-10% of gully head(D),** m

III. VELOCITY AT STIILING BASIN TOE, **$V=(2gh_e)^{0.5}$,** m/s

Where, g=9.81, m/s^2

IV. INITIAL DEPTH OF THE FLOW, **$y_1=Q/LV$,** m

V. FROUDE NUMBER, **$F_r=V/(g*y_1)^{0.5}$**

VI. SEQUENT DEPTH, **$y_2=y_1*0.5((1+8(F_r)^2)^{0.5}-1)$,** m

VII. FLOOR AND CHUTE BLOCK HEIGHT= **y_1**,m

VIII. SPACING AND WIDTH BETWEEN FLOOR AND CHUTE BLOCKS=**$0.75*y_1$**, m

IX. DISTANCE OF FLOOR BLOCKS FROM THE SIDE WALLS =**$0.375*y_1$**, m

X. TAIL WATER DEPTH OVER THE STILLING BASIN, **$y_2' = 1.4y_1*(F_r)^{0.45}$,** m

XI. STILLING BASIN LENGTH,**$L_B=4.5y_2/(F_r)^{0.38}$,** m

XII. SIDEWALL AND STILLING BASIN HEIGHT = **$(y_2/3)+y_2'$**,m

XIII. TRANSVERSE SILL HEIGHT = **$0.07*y_2$,** m

XIV. SIDE WALL FREE BOARD TO BE PROVIDED ABOVE THE TRAILED WATER DEPTH = **$y_2/3$,** m

XV. WING WALL HEIGHT= **$(y_2/3)+y_2'$**m

2.5.3 STRUCTURAL DESIGN OF THE CHUTE SPILLWAY

I. FORCES ANALYSIS

Forces can be analyze by using head of each section upstream, head of each section downstream, force per horizontal width of the water body as shown in Table 3.4. (Ghanshyam Das, 2012)

Table: 2.4 Force analyses for Chute spillway structure

Pressure diagram section no.	Head of each section up stream (m)	Head of each section downstr eam (m)	Force per horizontal width of the water body (m)	Pressure diagram area (m^2)	Uplift force (Kg)	Cumulative uplift force (Kg)	Weight of each section (Kg)	Cumulative weight of the structure (Kg)	Comments— safe when weight > the uplift force(Safe or Unsafe) (9)>7)
(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)	(10)
1	d	P=A-B	x/4	0.5(d+(A-B))*x/4	(5)*W*1000		W_t		
2	A-B	C-D	x/4	0.5*((A-B)+(C-B))*x/4	(5)*W*1000		W_t		
3	C-D	E-F	x/4	0.5*((C-D)+(E-F))*x/4	(5)*W*1000		W_t		
4	E-F	G-H	x/4	0.5*((E-F)+(G-H))*x/4	(5)*W*1000		W_t		
5	G-H	0.01	W_S	0.5*W_S*(G-H)	(5)*W*1000		Wt_s		

$$P=\left\{\frac{D+d}{x+ws}*\left((x+ws)-{}^{x}/_{4}\right)\right\}-\left\{\frac{D}{x}\left(x-{}^{x}/_{4}\right)\right\}$$

$$A=\left\{\frac{D+d}{x+ws}*\left((x+ws)-{}^{x}/_{4}\right)\right\}$$

$$B=\left\{\frac{D}{x}\left(x-{}^{x}/_{4}\right)\right\}$$

$$C=\left\{\frac{A}{(x+ws)-x/4}*\left((x+ws)-2\,{}^{x}/_{4}\right)\right\}$$

$$D=\left\{\frac{B}{(x-x/4)}*\left(x-2\,{}^{x}/_{4}\right)\right\}$$

$$E=\left\{\frac{C}{(x+ws)-2x/4}*\left((x+ws)-3\,{}^{x}/_{4}\right)\right\}$$

$$F=\left\{\frac{D}{(x-2x/4)}*\left(x-3\,{}^{x}/_{4}\right)\right\}$$

$$G=\left\{\frac{E}{(x+w\ )-3x/4}*\left((x+ws)-4\,{}^{x}/_{4}\right)\right\}$$

$$H=\left\{\frac{F}{(x-3x/4)}*\left(x-4\,{}^{x}/_{4}\right)\right\}$$

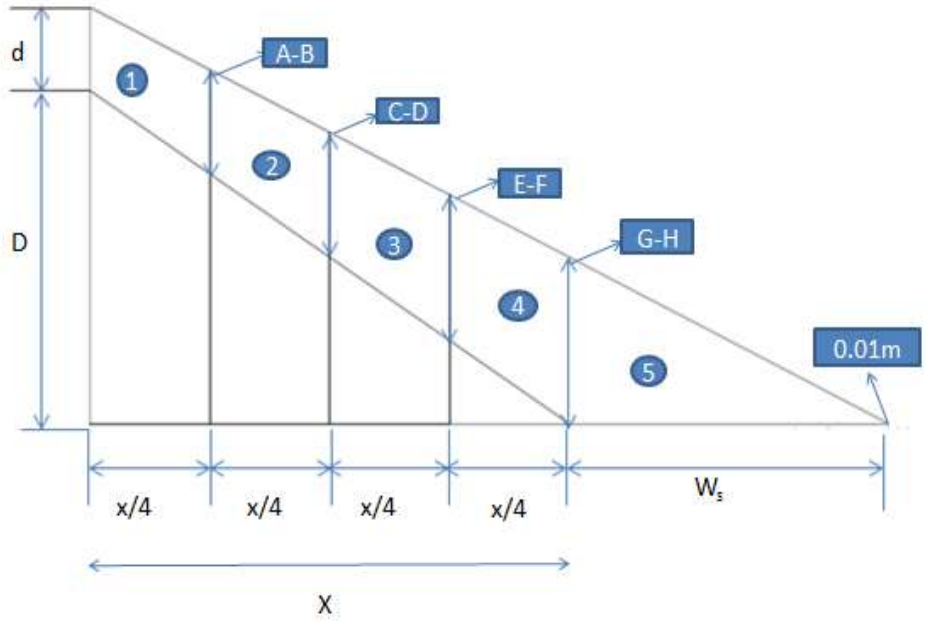

Fig. 2.10 Pressure diagram for chute spillway

II. THE WEIGHT OF THE SECTION OF STRUCTURE

=**Cross-sectional area of a section (L/4*W) *thickness (t)*density,** Kg

III. LENGTH OF THE TOTAL CHANNEL**(L)=(D^2+x^2)$^{0.5}$,** m

IV. LENGTH OF EACH SECTION=**L/4,** m

V. WEIGHT OF THE BASE OF EACH SECTION= **(L/4)*W*t*density,** Kg

VI. WEIGHT OF TWO SIDE WALLS ON EACH SECTION =**2*((L/4)*d*t*density),** Kg

VII. TOTAL WEIGHT OF EACH SECTION

(W_t)=((L/4)*W*t*density)+(2*((L/4)*d*t*density)), Kg

WEIGHT OF THE STILLING BASIN

VIII. WEIGHT OF THE BASE=**W_s*W*t* density,** Kg

IX. SUPPOSE THE HEIGHT OF SIDE WALLS OF THE STILLING BASIN=**0.7,** m

X. WEIGHT OF THE SIDE WALLS=**2*(W_s*0.7*t* density)**, Kg

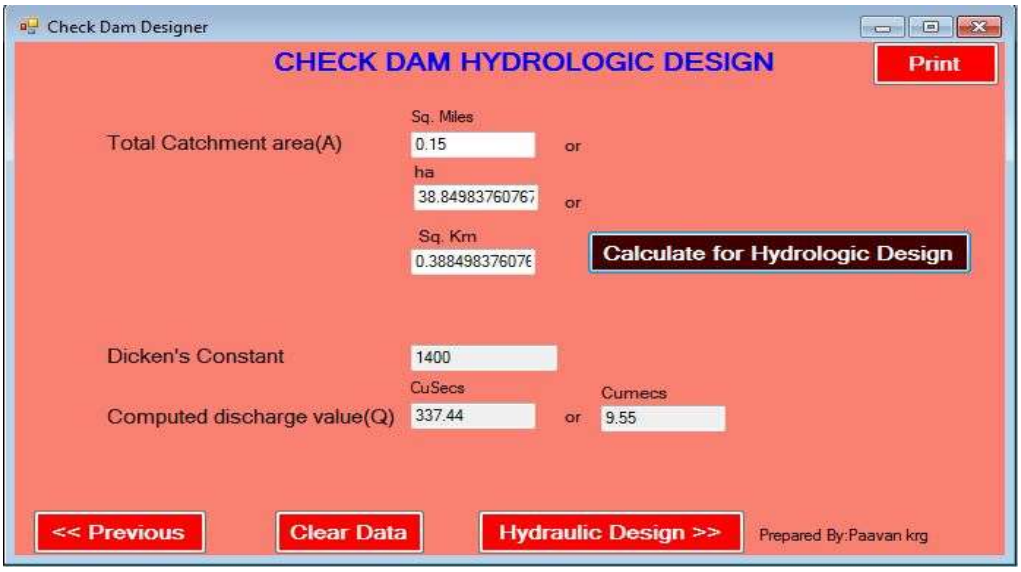
XI. TOTAL WEIGHT OF THE STILLING BASIN

(Wt_s)=(W_s*W*t* density)+(2*(W_s*0.7*t* density)), Kg

3. RESULTS AND DISCUSSION

Gully control structures, such as check dams, drop spillways, drop inlet spillways, and chute spillways, are developed using hydrologic, hydraulic, and structural stages.

3.1 Check Dam Design Hydrologic design for gully control structures is similar, but check dam design differs. Hydraulic and structural designs vary each structure. Using mathematical formulas from the previous chapter, structures are constructed in Visual Studio 13.3.1 Check Dam Design - Hydrologic design based on numerical formulas - Fig. 3.1 - Hydraulic design procedure - Fig. 3.2 - Structural design - Fig. 3.3 - Check dam discharging at maximum flood level - Fig. 3.4 - Check against



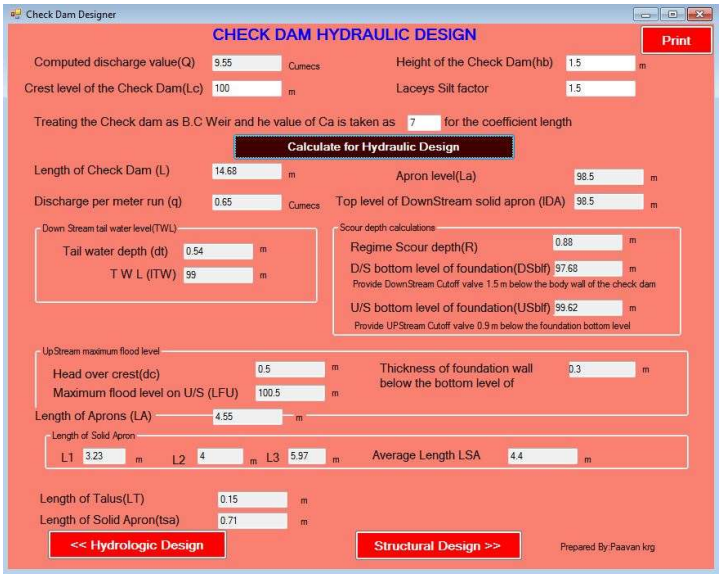


Fig.3.1. Hydrologic design of check dam

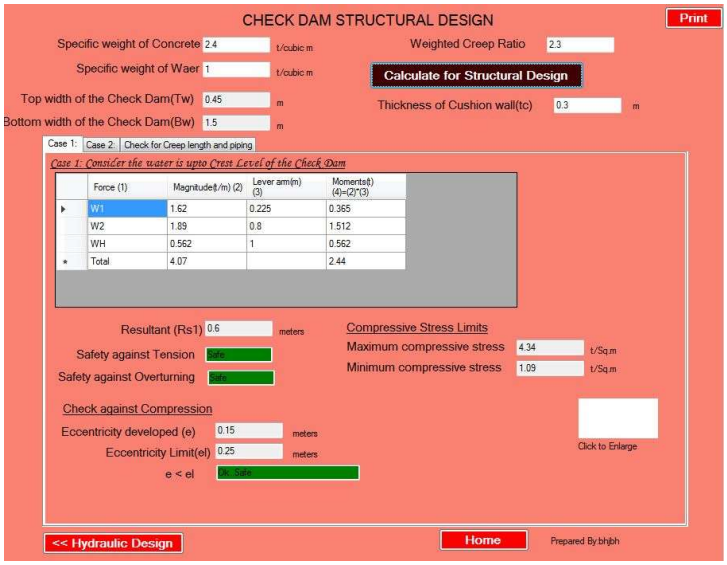

Fig.3.2. Hydraulic design of check dam **Fig.3.3. Water is up to crest level of check dam**

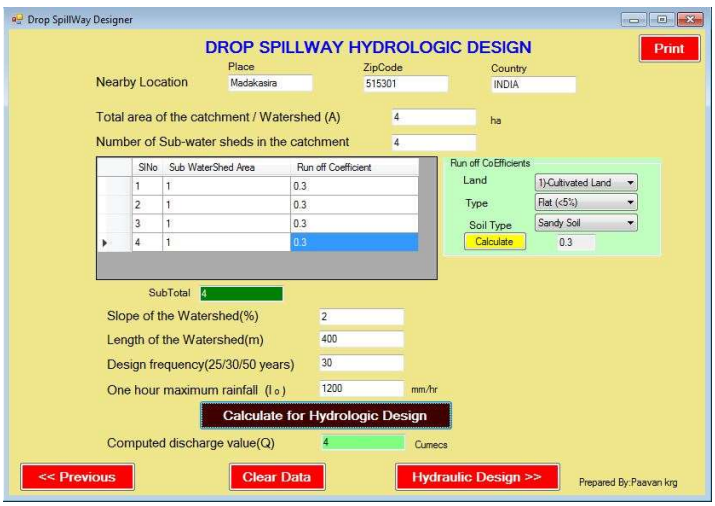

Fig.3.4. Check dam is discharging at maximum flood level

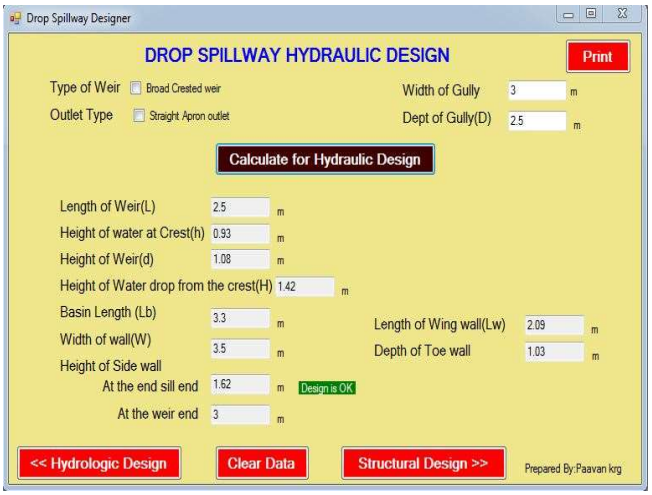
Fig.3.5. Check against creep length and piping

4.2 Drop spillway design

The hydrologic design of a drop spillway is determined by the rational formula, as shown in Figure 3.6. The hydraulic design process for the drop spillway is illustrated in Figure 3.7. Additionally, the structural design of the drop spillway is analyzed by force analysis.



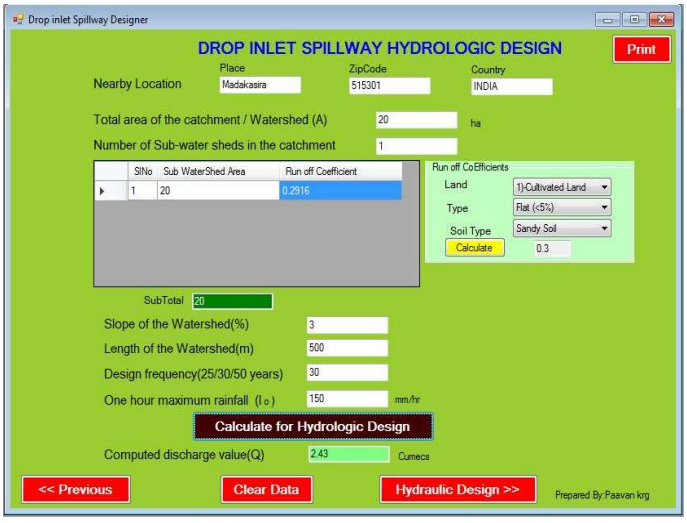


Fig.3.6. Hydrologic design of Drop Spillway **Fig.3.7. Hydraulic design of Drop Spillway**

4.3 Drop Inlet spillway design

The design of the drop intake spillway takes into account the hydrologic design, as shown in Figure 3.8, and the hydraulic design of the pipe spillway, which considers factors such as the percentage of pipe flow, as illustrated in Figure 3.9.

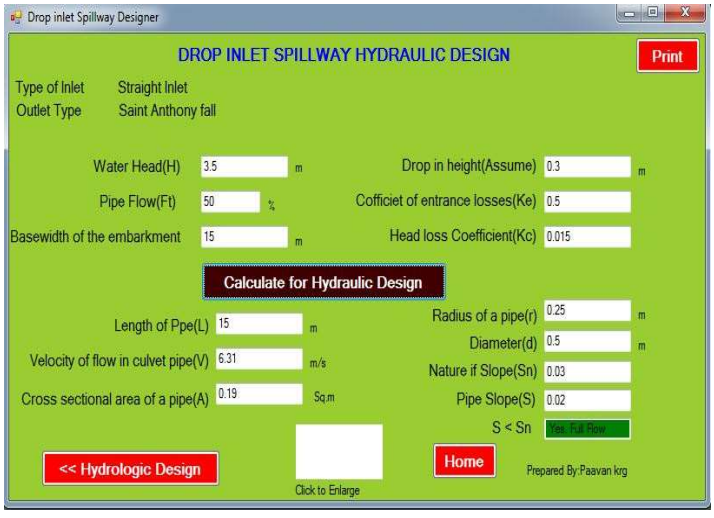

Fig.3.8. Hydrologic design of Drop Inlet Spillway **Fig.3.9. Hydraulic design of Drop Inlet Spillway**

3.4 Chute spillway design

The hydrologic design of a chute spillway is also determined by using the rational method for calculating the maximum flood flow, as seen in Figure 3.9. The dimensions of the chute spillway are determined by the hydraulic design technique, as seen in Figure 3.10. The structural design of the chute spillway involves the performance of strength and stability calculations.

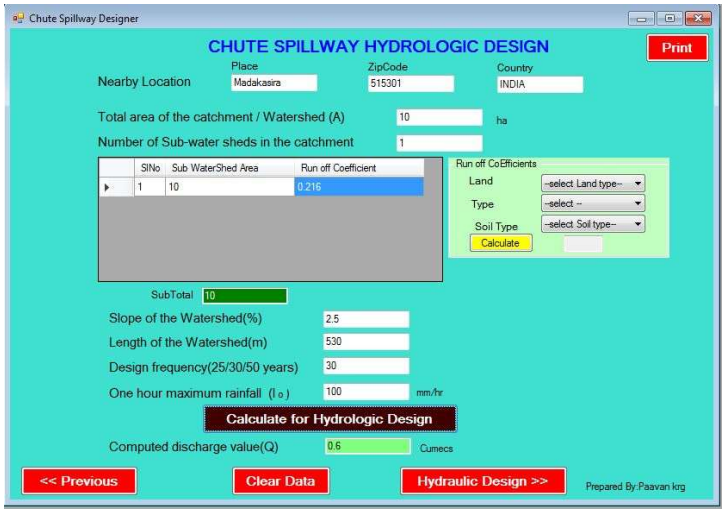

Fig.3.9. Hydrologic design of Chute Spillway

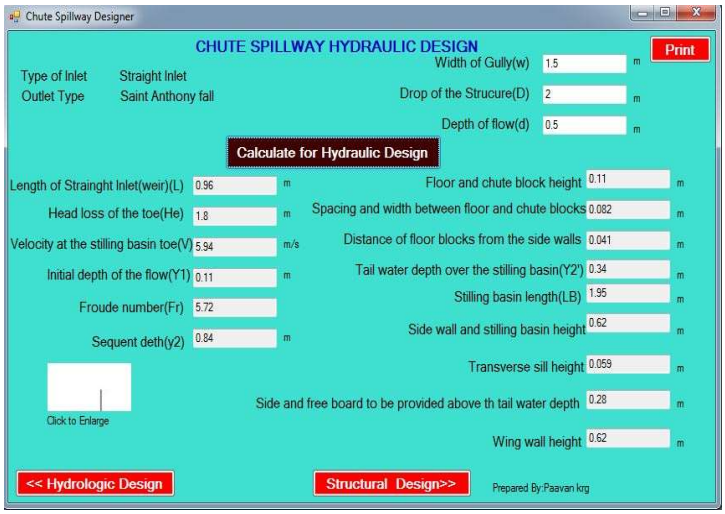

Fig.3.10. Hydraulic design of Chute Spillway

3.5 Validation of GCS_Designer for check dam

Table 3.1 shows the hydrologic, hydraulic, and structural design parameters computed by the program and compared to manual output or human computation for the check dam. GCS_Designer software and hand calculation yielded the same maximum flood discharge of 9.55 m3/s, hence no mistake was discovered.

The manual check dam length was 14.67 m and the GCS_Designer length was 14.68 m, and the truncation error was 0.0681 due to rounding. Except for length of apron 4.54 m and 4.55 m, length of solid apron 4.39 m and 4.40 m, and thickness of solid apron 0.70 m and 0.71 m for manual and GCS_Designer, the remaining hydraulic design parameters have similar values in both outputs and zero percentage error.

In two cases, structural design parameters have split. In circumstance 1 (water up to the check dam crest), manual and GCS_Designer had maximum compressive stress of 4.37 and 4.34 t/m2 and minimum of 1.06 and 1.09 t/m2. Maximum and lowest compressive stresses have -0.6192% and 2.7523% errors.

In case 2 (check dam discharge at maximum flood level), manual and GCS_Designer had maximum compressive stress of 4.93 and 4.90 t/m2 and minimum of 2.25 and 2.31. Maximum and lowest compressive stresses have errors of -0.6122% and 2.5974%.

Manual and GCS_Designer creep lengths were 12.34 m and 12.36, with weighted creep ratios of 4.25 and 4.26. Creep length and weighted creep ratio have 0.1618 and 0.2347 percentage errors. Table 4.1 creep length for structural design was correct.

GCS_Designer validation in check dams yielded 2.7523 % error for minimum compressive stress and 0.0681 % inaccuracy for length. Validating GCS_Designer for check dam involves 25 parameters. 10 parameters have % errors while the rest have zero. The remainder are under estimate (negative) and 80% are above estimate (positive).

Table: 3.1. Validation of GCS_designer for check dam

Design parameter	Manual output	GCS_Designer output	% of Error	Remarks
Hydrologic Design				
Computation of maximum flood discharge (Q),m^3/s	9.55	9.55	0.0000	do
Hydraulic Design

Creep length provided (CLP), m	12.34	12.36	0.1618	Truncation
Weighted creep ratio (C_W)	4.25	4.26	0.2347	Truncation

3.6 Validation of GCS_designer for drop spillway structure

GCS_Designer software and hand calculation yielded the same maximum flood discharge of 4.00 m3/s, hence no mistake was discovered.The height water at the crest was 0.93 m and 0.96 m (error = -3.2258 %), the weir was 1.08 m and 1.11 m (error = -2.7778 %), the water drop from the crest was 1.42 m and 1.39 m (error = 2.1127 %), the basin apron was 3.30 m and 3.27 m (error = 0.9091%), and the wing wall was 2.09 m and 2.16 m (error = -3.3493%). The weir crest length, side wall width, and side wall height were correct. In structural design of drop spillway, total uplift pressure was 0.92 m in both outputs, therefore no mistake occurred. The findings were in Table 4.2. GCS_Designer validation in drop spillway showed -3.3493 % error for wing wall length and -0.0309 % error for head wall extension at end sill end. Out of 12 parameters analyzed for GCS_Designer drop spillway validation, 7 exhibit % error and the rest show zero. 28.6% of drop spillway values are above estimate and 71.4% are under estimate.

Table: 3.2. Validation of GCS_designer for Drop Spillway Structure

Design parameter	Manual output	GCS_Designer output	% of Error	Remarks
Hydrologic Design				
Computed discharge value (Q),m^3/s	4.00	4.00	0.0000	do
Hydraulic Design				
Length of weir crest (L),m	2.50	2.50	0.0000	do
Height of water at crest (h),m	0.96	0.93	-3.2258	Truncation
Height of the weir (d),m	1.11	1.08	-2.7778	Truncation
Height of water drop from the crest (H),m	1.39	1.42	2.1127	Truncation
Basin apron length (Lb),m	3.27	3.30	0.9091	Truncation
Width of the side wall (W),m	3.50	3.50	0.0000	do
Length of the wing wall(Lw),m	2.16	2.09	-3.3493	Truncation
Depth of the toe wall, m	1.06	1.03	-2.9126	Truncation
At the end sill end, m	1.67	1.62	-0.0309	Truncation
At the weir end, m	3.00	3.00	0.0000	do
Structural Design				
Total Uplift Pressure (P_u),m	0.92	0.92	0.0000	do

3.7 Validation of GCS_designer for Drop Inlet spillway

The discharge value of 2.43 m3/s was determined for both the manual calculation and the output from the GCS_Designer program. The velocity of the flow in the culvert pipe was measured to be 6.31 m/s and 6.30 m/s (with an error of 0.0016%) for the GCS_Designer software output and manual output, respectively. However, no error was observed in the measurements of the pipe's length (15 m), cross-sectional area (0.19 m2), radius (0.25 m), natural slope (0.03%), and pipe slope (0.02%), as indicated in Table3.3. The user's text is incomplete and does not provide any information. The validation of GCS_Designer was seen in the drop inlet spillway, resulting in a velocity of flow in the culvert pipe with an inaccuracy of 0.0016%.

The validation of GCS_Designer for drop inlet spillway involves the consideration of a total of 8 parameters. Among these parameters, one parameter exhibits a percentage of error, while the rest

parameters exhibit zero % error. A mistake has been observed in the drop inlet spillway among a total of 8 parameters, while the remaining 87.5% of values do not exhibit any errors.

Table: 3.3. Validation of GCS_designer for Drop Inlet Spillway

3.8 Validation of GCS_designer for Chute spillway

The discharge value of 0.60 m3/s was determined using the GCS_designer program, and no errors were detected throughout the hydrologic design process. The Froude numbers were determined to be 5.72 and 5.85, with an error of -2.2727%. The sequent depths were measured to be 0.84 m and 0.82 m, with an error of 2.3810%. The spacing and width between the floor and chute blocks were found to be 0.082 m and 0.08 m, with an error of 2.4390%. The distance of the floor blocks from the side walls were measured to be 0.041 m and 0.04 m, with an error of 2.4390%. The tail water depth over the stilling basin was determined to be 0.34 m and 0.33 m, with an error of 2.9412%. The length of the stilling basin was measured to be 1.95 m and 1.85 m, with an error of 3.0769%. The height of the sidewall and stilling basin was found to be 0.62 m and 0.60 m, with an error of 3.2258%. The transverse sill height was measured to be 0.059 m and 0.06 m, with an error of -1.6949%. The side wall free board above the trailed water depth was determined to be 0.28 m and 0.27 m, with an error of 3.5714%. The wing wall height was measured to be 0.62 m and 0.60 m, with an error of 3.2258%. The GCS_Designer software output and manual output yielded these results, with no errors found in the remaining parameters of the hydraulic design of the chute spillway, as presented in Table 3.4.

Design parameter	Manual output	GCS_Designer output	% of Error	Remarks
Hydrologic Design				
Computed discharge value (Q),m3/s	2.43	2.43	0.0000	do
Hydraulic Design				
Length of pipe (L),m	15.00	15.00	0.0000	do
Velocity of flow in culvert pipe (v), m/s	6.30	6.31	0.0016	Truncation
Cross sectional area of a pipe (A), sq.m	0.19	0.19	0.0000	do
Radius of a pip(R),m	0.25	0.25	0.0000	do
Diameter of a pipe(d),m	0.50	0.50	0.0000	do
Natural slope (Sn), %	0.03	0.03	0.0000	do
Pipe slope(S), %	0.02	0.02	0.0000	do

Table: 3.4. Validation of GCS_designer for Chute Spillway

The chute spillway's structural design parameters were length of the total channel 3.61 m and 3.6 m

Design parameter	Manual output	GCS_Designer output	% of Error	Remarks

Spacing and width between floor and chute blocks, m	0.08	0.082	2.4390	Truncation
Distance of floor blocks from the side walls, m	0.04	0.041	2.4390	Truncation
Tail water depth over the stilling basin(Y2'),m	0.33	0.34	2.9412	Truncation
Stilling basin length(LB),m	1.89	1.95	3.0769	Truncation
Sidewall and Stilling basin height, m	0.60	0.62	3.2258	Truncation
Transverse sill height, m	0.06	0.059	-1.6949	Truncation
Side wall free board to be provided above the trailed water depth, m	0.27	0.28	3.5714	Truncation
Wing wall height, m	0.60	0.62	3.2258	Truncation
Structural Design				
Horizontal length of spillway(x),m	3.00	3.00	0.0000	do
Length of the total channel(L),m	3.60	3.61	0.2770	Truncation
Length of each section, m	0.90	0.90	0.0000	do
Weight of the base of each section, kg	466.70	466.75	0.0107	Truncation
Weight of two side walls on each section, kg	310.20	310.50	0.0966	Truncation
Total weight of each section(W_t), kg	778.35	778.41	0.0077	Truncation
Weight of the stilling basin				
Weight of the base, kg	1035.00	1035.00	0.0000	do
Weight of the side walls, kg	965.00	966.00	0.1035	Truncation
Total weight of the stilling basin(Wts), kg	2000.00	2001.00	0.0500	Truncation

(error = 0.2770%), weight of each section's base 466.75 kg and 466.70 kg (error = 0.0107%), weight of two side walls 310.50 kg and 310.20 kg (error = 0.0966%), total weight of each section 778.41 kg and 778.35 kg (error = 0.0077%), and weight of the stilling basin side walls 966 kg and 965 kg (error = 0.1035%). For GCS_Designer software output and manual output, chute spillway structural design was error-free. Horizontal length was 3.0 m, section length was 0.9 m, and stilling basin base weight

was 1035 kg. GCS_Designer proved valid in chute spillway with 3.5714 % error for side wall free board above tail water depth and 0.0077 % error for total section weight. 16 of the 25 parameters analyzed for GCS_Designer chute spillway validation exhibit percentage of error, while the rest show zero percentage error. 87.5 % and 12.5% values were over estimate and under estimate, respectively.

ABSTRACT

Agricultural regionalization is a process of Delineating on area in to territorial units of complexes of uniformities on the basis of physical factors like climate, soils, vegetation, and availability of water, farm size and socio-economic parameter. It has a significant bearing on the development of agricultural and regional planning in developing countries. It is needed to understand Agricultural types, variations, challenges, forecast productivity, feature plans for agricultural developments, suggest optimal land utilization patterns, and make an inter-regional comparison in different aspects and so on. Agriculture is one of the leading occupations in India. It is back bone of Indian economy. In India nearly about 64 % of the total population and 90 % of rural population is engaged in agriculture. India being a country of Intensive subsistence farming activities are observed all-round the year in various intensities. Understating the importance of regionalization, specifically crop regions; an attempt is made in the present study, to demarcate the crop regions of Kurnool district for two time periods i.e., 2007-08 & 2018-19.

Keywords : *Primary crop region, Secondary crop region, Tertiary crop region Ranking Method, and Change of crop regions***.**

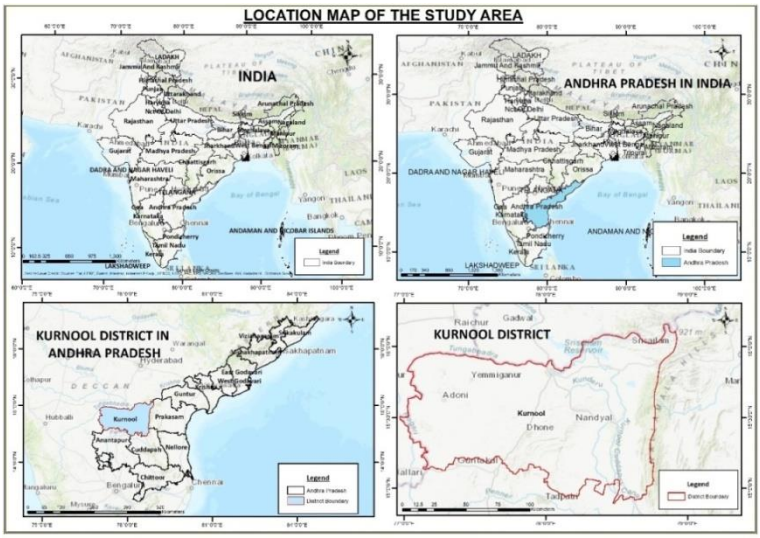
INTRODUCTION

Agriculture is an important occupation which is considered as a part and parcel

of human life and which runs through a definite process. It is carried under the control of natural environment. Agriculture is an important source of food. In spite of growing industrialization and urbanization in the world. In developing countries agriculture sector has been a major source of employed and income. Agriculture is a backbone of Indian economy. In India near about 64 % of the Total population and 90 % of rural population is engaged in agriculture. In spite of technological development, environmental factors play key role in the Development of agriculture in the region. Socio-economic factors also support for the growth of agriculture. This it is necessary to focus on the physical and Socio-economic Factors of the study region to understand the agricultural scenario of the region.

Agricultural regionalization is one of the oldest concepts in Agricultural classification and has a significant bearing on regional planning and development of agriculture in developing countries. It is regarded as a device for clustering both visible and non-visible Agricultural phenomena on the earth surface. Such device enables geographers to divide an area in to several regions in terms of diversity present in agricultural system. It gives us the relative position of crops on regional scale (Dayalan N.2018). The analysis of general land use, agricultural regionalization and cropping pattern helps to denote the intensity and status of farming in an area and also helps in the formulation of Agricultural plans which may go a long way in reducing the regional disparities and inequalities.

Systematic study of crop regions is of great significance for a comprehensive and clear understanding of the agricultural mosaic of an agro-climatic region and the planning and development of its agriculture, in recent years the concept of crop regions has engaged the attention of geographers and agricultural land use planners.



The first attempt of agricultural regionalization of Europe was made by *Jonsson* (1926) in his work Agricultural regions of Europe. Baker (1926), one of the Leading American Geographers, published Agricultural regions of North America, and Jones (1928) produced his book Agricultural regions of South America. Similarly, Taylor (1930) Delineated agricultural regions of Australia and Valkenberg (1931) divided Asia into Agricultural Regions. The first attempt to classify types of agricultural land use the world over, in terms of agricultural element – complexes, was in the form of the empirical system developed by Jones and Whittlesey (1932). A few of Russian authors who have put forwarded their views regarding Agricultural regionalization, Marshall (1787), Arsenev (1818), (Raktinika, 1959, 1971, 1973, 1975, 1979). Others have attempted to demarcate regions by aggregation of basic areal units based on agriculture with the help of quantitative taxonomic methods (Hartshorne and Dicken 1935, Nordgard 1974).

In India, geographers richly contributed to the studies of agricultural geography on various aspects including cropping intensity, crop combinations, crop concentration, crop diversification, agricultural efficiency, agricultural classification, agricultural regionalization, agricultural typology of which brought about lot of changes in the subject matter, approaches and methodology of agricultural geography. Deshpande (1942, 1964), Mukherjee (1942), Dayal (1950) etc. made regional studies in agricultural geography. Chatterjee (1952, 1956), Shafi (1960), Singh (1962), Bhatia (1967), Mishra (1969), Raifullah, Jasbir Singh (1972) etc. are among the notable agricultural geographers in India.

LOCATIONAL SETTING OF KURNOOL DISTRICT

Kurnool district is the south-western district of Andhra Pradesh and lies approximately between 14º54' to 16º18' North Latitudes and 76º58' 79º34' East Longitudes. The altitude of the district varies from 100 ft above the mean sea

level. This district is bounded on the north by Tungabhadra and Krishna River as well as Mahbubnagar district, on the south by Kadapa and Anantapur district, on the west by Bellary district of Karnataka state and on the east by Prakasam District. The district ranks 10 in population with 40, 53,463 people accounting for 4.63 % of the total population of the state as per 2011 Population census. While in area it occupies the 3rd place 17658 sq.km. which account for 6.41% of the total area of the state. The Nallamala and Earramalla are two important mountain ranges in the district running in parallel from North to south. Earramla divided the district into two well defined tracks from east to west in terms of soils. The Kurnool District is a combination of Red, Block and sandy soils. It has facility of Irrigation through canals (K. C. Canal, Tungabadra project low level canal and hundri neva sujalasravanthi project), tanks, wells, and river sources. The district has typically geographical aspects and climatic variation comparatively from other districts of Rayalaseema region of Andhra Pradesh. The district is well connected with road and rail transportation with national highways to farmer capital city of Andhra Pradesh.

OBJECTIVES

To identify and demarcate the crop regions such as primary, secondary and tertiary crop regions of Kurnool district for the years 2007-08 and 2018-19.

To study the changes in crop regions during 12 years period.

DATA AND METHODOLOGY

In the present study, secondary data pertaining to general cropping pattern for two time periods i.e., 2007-08 and 2018-19 have been collected from the Government records and reports from the Chief Planning Officer, Handbook of Statistics, Agricultural Department of Kurnool district taking 'Mandal' as Unit. Simple statistical techniques such as percentages and averages have been used to analyze the data. The spatial patterns of various crops that ranked from first to third in percentage of total cropped area is attempted here for the study of Primary, Secondary and Tertiary crop regions. The task of the first order crop regions (or) first ranking crop regions is accomplished by considering the crops which account for the maximum percentage of the total cropped area in each of the component areal units, no matter what percentage it occupies in the total cropped area. In the same way, the second-order crop regions and third-order crop regions have been demarcated on the basis of their percentage in order. To fulfill the set objectives, percentages of different crops that are growing in the district have been calculated and arranged in descending order, to demarcate the crop regions.

PRIMARY CROP REGIONS (2007-2008)

During the study period, out of 10 crops, only four crops namely Pulses (22 mandals), Ground nut (13 Mandals), Sunflower (10 mandals) and Paddy (8 Mandals) were registered as primary crops in different mandals with different concentration and one mandal srisailam which is in north eastern part of the district is 100 % covered with forest. Pulses occupied first place in the Maximum no of mandals and paddy crop in the minimum no of mandals in the district.

PULSES REGION

Pulses crop is dominant primary crop region in the study period occupying in

the district. It formed the largest region as primary crop. Pulses are one of the important food crops globally due to their higher protein content. Pulses are an important group of crops in India which is also responsible for yielding large financial gains by amounting to many exports. Pulses form an integral part of the Indian diet provides much needed protein to the carbohydrate –rich diet. India is largest producer of pulses in the world. In India the main regions with high productivity are Punjab, Haryana, western UP, West Bengal Delta region, Coastal A.P, Tamil Nadu, Kerala, Coastal and eastern Karnataka, and some parts of Maharashtra. In Kurnool it occupied about 269832 Hectares. In about 22 mandals of the district spread over in most of the south western, south-eastern, north-eastern part of the district. (Table 1 & Fig. 1).

GROUNDNUT REGION

Groundnut crop is the second –largest crop region in the study period occupying 13 mandals of the district. Groundnut is a leguminous plant that is widely cultivated in the tropics and subtropics. It is valued for its high oil edible seeds and as such, it is the fourth most important source of edible oil and a third most important source of vegetable protein and an important agricultural export commodity. In India, after Gujarat, Andhra Pradesh occupies 2nd place in groundnut production. In the actual area, it occupied about **236972** hectares. In About 13 Mandals of The district, Namely C.Belagal, Dhone, Bethamcherla, Veldurthy, Krishna Giri, Peapully, Kosigi, Pedda Kadubur, Yemmiganur, Pattikonda, Devanakonda, Tuggali, Gonegandla, mostly confined to the central, south and north western part of the district (Table 1 & Fig. 1).

SUNFLOWER REGION

Another important primary crop region in Kurnool District is sunflower spreading over 10 mandals. In the actual area, it occupied about *157104* hectares. The mandals where the sunflower region is dominant as the primary

crop region are Kallur, Kodumur, Atmakur, Kothapalle Gadivemula, Adoni, kowthalam, Nandavaram, mantralayam, Holagunda mandals, which are located in western, north, north eastern part of the district. (Table 1 & Fig. 1)

PADDY REGION

As primary crop region, paddy crop spreading over 8 Mandals, namely Velogode, Pamulapadu, Nandayala, Mahanandi, B. Atmakur, Rudra varam, sirvella, Gospadu which are distinctly seen in the eastern part of the district in Andhra Pradesh, it is mainly cultivated in the Krishna, Guntur, Kurnool, Nellore Prakasham, and twin Godavari district Kurnool sonamasoori rice is popularly fine rice variety being cultivated in Rayalaseema, especially in Kurnool due conductive atmosphere. (Table 1 & Fig. 1).

PRIMARY CROP REGIONS (2018-2019)

During the year 2018-19, 5 crops have been noticed under primary crop region in Kurnool District. They are cotton (17 Mandals), Pulses (15 Mandals), paddy (9 Mandals), millets (8mandals), Ground nut (4 mandals).

COTTON REGION

In 2018-19 cotton crop is dominant primary crop region. Cotton is one of the most important fiber and cash crop of India and plays a dominant role in the industrial and agricultural economy of the country. It provides the basic raw material (cotton fiber) to cotton textile industry. Cotton in India provides direct livelihood to 6 million farmers and about 40 - 50 million people are employed in cotton trade and its processing. In India, there are ten major cotton growing states namely Punjab, Haryana, Rajasthan, Madhya Pradesh, Maharashtra, Gujarat, Andhra Pradesh, Telangana, Karnataka, and Tamil Nadu.

Cotton region is newly formed primary crop region during the period 2018-19 replacing the sunflower, ground nut and pulses crops. The actual area it occupied in this district about 259498 hectares and spread over 17 mandals especially located in Western and northern part of the district. It is emerged as the largest crop region in the study is during 2018-19. (Table 1 & Fig. 1)

PULSES REGION

This is 2nd largest crop regions occupying the 15 mandals during the study period, confined mostly to the north, south, south eastern part of the district. (Table 1 & Fig. 1)

PADDY REGION

As a primary crop region, paddy crop is reported 9 mandals of the district, especially located in eastern part of the district. (Table 1 & Fig. 1)

MILLETS REGION

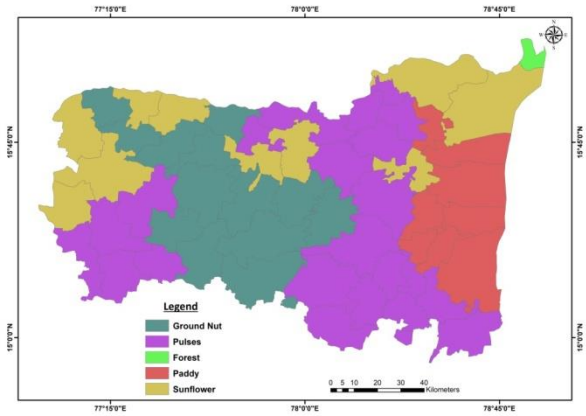
Eight mandals namely Pagidayala, Jupadubunglow, Atmakur, Pamulapadu, kothapalle, Gadivemula, Allagada, Chagalamari are reported as primary crop regions with millets in the Study period (Table 1 & Fig. 1).

GROUND NUT REGION

Ground nut as a primary crop region has been noticed in only four mandals namely Dhone, Krishna giri, Devanakonda, Tuggali located in central part of the district. (Table 1 & Fig. 1)

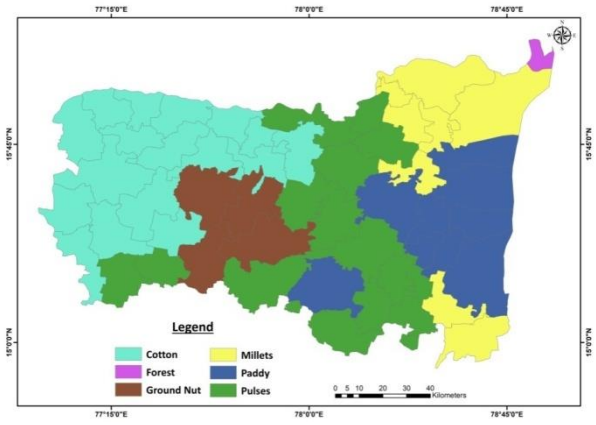
CHANGE IN PRIMARY CROP REGIONS (2007-08 & 2018-2019)

Noticeable changes have occurred in primary crop regions of the district during 12 years' period. Among the 4 primary crop regions which are registered in 2007-08, namely pulses, groundnut, sunflower, and paddy have been noticed.



After 12 years' period, new crops Cotton and millets were registered. The other changes are, increase in the number of mandals regarding paddy crop region (+ 1 mandals). A decrease in the number of mandals has been seen in the pulse's region (-7mandals) and ground nut region (-9 mandal) and sunflower crop remarkably decrease and not registered in 2018-19. New regions i.e., the Cotton and Millets regions have emerged with 17 and 8 mandals that previously belonged to the sunflower, groundnut and pulses region (Fig. 1 & Table 1).

Table – 1



Primary crop regions in Kurnool District 2007-08 & 2018-19

S. No.	Crops in Primary Crop Region	No of Mandals in each Individual Crop Region		Decrease / Increase in the Number of Mandals during 12 Years Period
		2007-2008	2018-2019	
1	Pulses	22	15	-7
2	Ground Nut	13	4	-9
3	Sunflower	10	0	-10
4	Paddy	8	9	1

7	**Total**	**53**	**53**	-

Fig. 1

Kurnool District Primary crop Regions 2007-2008

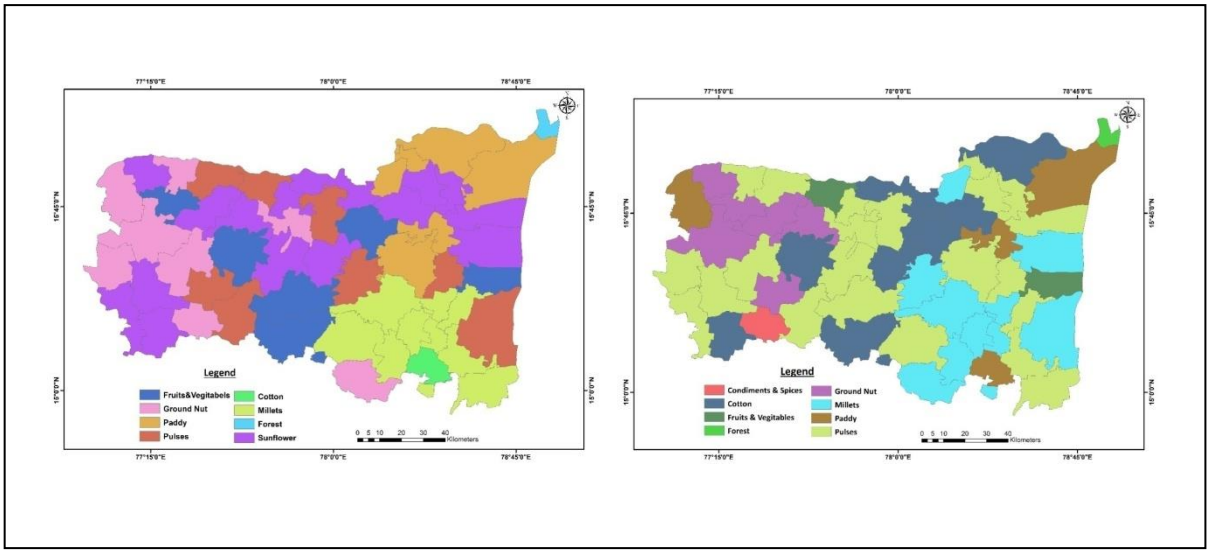
Kurnool District Primary crop Regions 2018-19

SECONDARY CROP REGIONS (2007-08)

Seven crops have been reported in secondary crop regions during the year 2007-08. The maximum number of mandals is in sunflower region found (15 mandals) fallowed by millets region (9 mandals), Pulses (8 mandals), Ground nut (8 mandals), Paddy (6 mandals), Fruits and vegetables (6 mandals) and cotton (1mandal). (Table-2 & Fig. 2)

SECONDARY CROP REGION (2018-19)

During 2018-19, about seven crops gained ground under secondary crop regions. Among these seven crops, Pulses region dominated with 22 mandals fallowed by millets region (10 mandals), cotton (8 mandals), Ground nut (6 mandals), Paddy (4mandals), Fruits and vegetables (2 mandals) and Condiments and spices (1 mandal). Sunflower has lost its place in the secondary crop regions during the study period. Condiments and spices came up as a new crop in the secondary crop region (Table 2 & Fig. 2).



CHANGES IN THE SECONDARY CROP REGION (2007-08 TO 2018-19)

Table -2

Secondary crop regions in Kurnool District 2007-08 & 2018-19

S. No.	Crops in Primary Crop Region	No of Mandals in each Individual Crop Region		Decrease / Increase in the Number of Mandals during 12 Years Period
		2007-2008	2018-2019

Kurnool District secondary crop regions 2007-08

Kurnool District secondary crop regions 2018-19

During 2007-08, seven crops have been recorded under secondary crop regions and the year 2018-19 also seven crops formed secondary crop regions. An increase in the areal spread has been observed in pulses (14 mandals), cotton (7 mandals), Millets (1 mandal) and condiments and spices (1 mandal). Decrease in the number of mandals has been found in fruits and vegetables (4 mandals), Ground nut (2 mandals) and paddy (2 mandals). Sunflower has lost its place in the secondary crop regions. Condiments and spices crop region is the new secondary crop region reported in 2018-19.

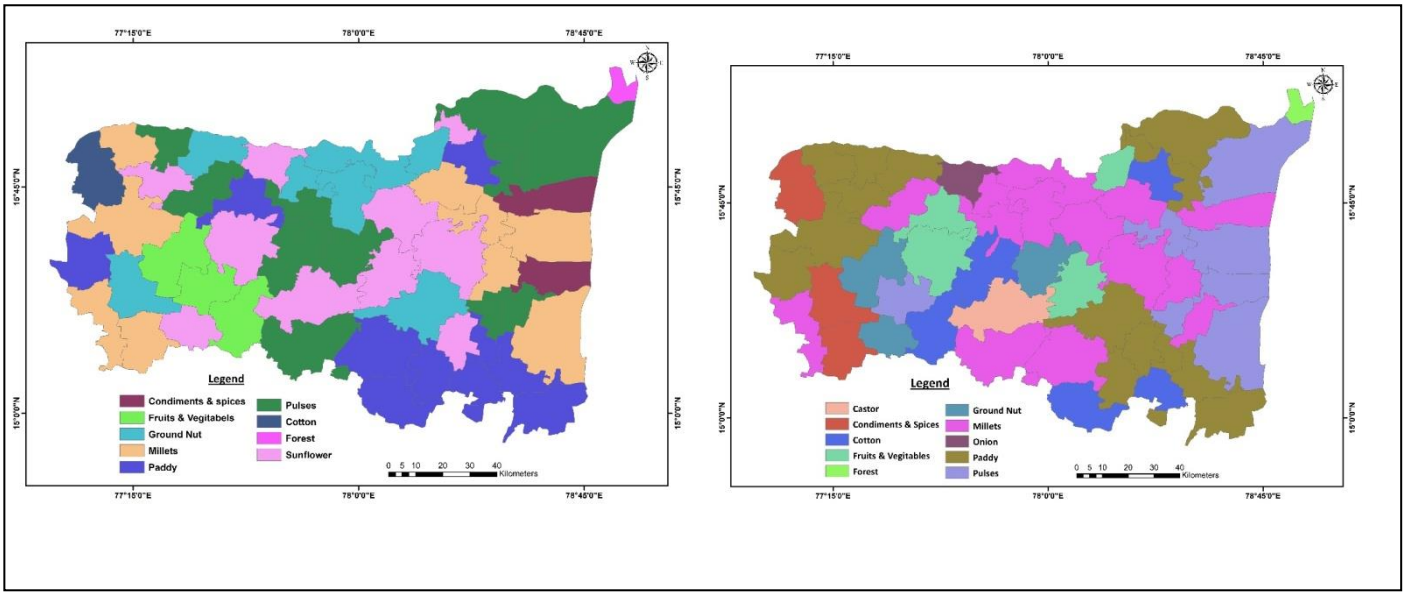
TERTIARY CROP REGIONS (2007-08)

In 2007-08, as many as 8 crops have emerged as the third ranking crops in the district, among which pulses (11 mandals) fallowed by sunflower (10 mandals), paddy (10 mandals), millets (9 mandals), Ground nut (7 mandals), Fruits and vegetables (3 mandals), condiments and spices (2 mandals) and cotton (1 mandal). (Table 3 & Fig. 3).

TERTIARY CROP REGIONS (2018-19)

During the year 2018-19, 9 crops have been noticed under tertiary crop regions with varied intensity. Paddy crop region is emerged as the largest tertiary crop region with 15 mandals fallowed by Millets (14 mandals), pulses (7 mandals), cotton (5 mandals) fruits and vegetables (4mandals), Ground nut (3 mandals), condiments and spices (3mandals), onions (1 mandal) and castor (1 mandals). sunflower has lost its place in the secondary crop regions. Onions and castor crop regions are the new secondary crop regions reported in 2018-19. (Table 3 & Fig. 3)

Table - 3



Tertiary crop regions in Kurnool District 2007-08 & 2018-19

S. No.	Crops In Primary Crop Region	No Of Mandals In Each Individual Crop Region		Decrease /Increase In The Number Of Mandals During 12 Years Period
		2007-2008	**2018-2019**	
1	Pulses	11	7	-4
2	Ground Nut	7	3	-4
3	Sunflower	10	-	-10
4	Paddy	10	15	5
5	Cotton	1	5	4
6	Millets	9	14	5
7	Fruits &Vegitables	3	4	1
8	Condiments &Spices	2	3	1
9	Onions	-	1	1
10	Castor	-	1	1
		53	53	-

Totally about 10 crops have been reported in the study period under tertiary crop regions. They are pulses, Groundnut, sunflower, paddy, cotton, Millets, fruits and vegetables, condiments and spices, Onions and castor. A decrease in the number of mandals each tertiary region during the 12 years is observed in pulses (-4 mandals) and Ground nut (-4 mandals). Increase in the number of mandals under each tertiary crop region during the 12 years of study period is noticed paddy (5mandals), millets (5 mandals) cotton (4 mandals), Fruits and

vegetables (1 mandals) and condiments and spices (1 mandals). Onions and castor crop regions are the new secondary crop regions reported in 2018-19. Sunflower tertiary crop region is absent during the 2018-19.

Kurnool district Tertiary crop regions 2018-19

CONCLUSION

During the agricultural year 2007-08, Kurnool District in India exhibited four primary crop regions, which included Pulses, Groundnut, Sunflower, and Paddy. However, in the subsequent agricultural year of 2018-19, there was a significant decline in the Sunflower crop region, and it was no longer registered in the district's agricultural landscape. In addition to the existing primary crop regions, Cotton and Millet crop regions emerged previously encompassed within the regions of Sunflower, Groundnut, and Pulses. Regarding the secondary crop regions, the year 2007-08 saw a total of seven crop regions. Unfortunately, in 2018-19, Sunflower lost its place among the secondary crop

regions, and a new crop region, namely Condiments and Spices, emerged, resulting in a total of seven secondary crop Regions.

In both years, 2007-08 and 2018-19, the district reported eight different crop regions at the tertiary level. However, in 2018-19, the Sunflower tertiary crop region was absent, and instead, Castor and Onion regions emerged, replacing one of the tertiary crop regions from 2007-08, namely sunflower. The agricultural landscape of Kurnool District underwent notable changes between 2007-08 and 2018-19. Sunflower experienced a significant decrease and was no longer present in both secondary and tertiary crop regions. Meanwhile, new crop regions like Cotton, Millet, Condiments, and Spices emerged, showcasing the dynamic nature of agriculture in the region over the year.

(ESTD : 1962)

THE DECCAN GEOGRAPHICAL SOCIETY, INDIA

The Deccan Geographical Society, India established in 1962 at Hyderabad (India) and started publication of Geographical Journal, namely, **"The Deccan Geographer"** since 1962 and **"Bhugol- Shastra Sansodhak"** Journal (Marathi+Hindi and English) since 2006. The journals are devoted to the publication of research papers in the diverse fields of Geography. Papers are invited on any of the themes involving the application of Geographical methodology and the research towards the solution of human problems. It includes papers on recent techniques and currents problems which deal with the issues related to the Environment, Social, Urban, Population and Food Security. The membership of journal is open for geographers, research scholars, planners, decision makers and allied disciplines. The interested persons can enroll for 5 years membership. The membership form is available on DGSI website:

IDENTIFYING THE TRUE COST OF NITRATE CONTAMINATION IN THE MID-GANGETIC PLAIN, BIHAR (INDIA): WHO'S PAYING FOR THOSE COSTS AND WHO'S RECEIVING THE BENEFITS

Narender Singh

Abstract

The Mid-Gangetic Plain (MGP) covers an area of 99,058 km^2 & is a lifeline for millions of people who rely heavily on groundwater. Although this is a region rich in rivers, more than 80% of the irrigation needs of the Bihar plains are met by groundwater, mainly due to easy access, unpredictability and poor irrigation networks. This has led to a rapid decline in water quality and quantity in shallow aquifers. This research aims to understand how nitrate contamination in the groundwater of the MGB has developed over time & comprehend the specific impacts on the rural communities of India particularly those facing socio-economic challenges. Given that a substantial 80% of India's populace resides in these rural regions, understanding & addressing these implications is of paramount importance. The weighted average water quality index (WAWQI) shows that 20.2% of groundwater is unfit for drinking. Surface water irrigation in the 19th century, the introduction of nitrogen-intensive crops (i.e. wheat, rice & sugarcane etc.) & pesticide at higher rate in the 20th century, urban development and groundwater irrigation intensified agricultural activity in the Indo-Gangetic Plain. Furthermore, the districts of South Bihar, compared to North Bihar, naturally receive a disproportionate amount of irrigation water from the Ganga and its tributaries. Additionally, during the non-monsoon season (November to June with little rainfall), groundwater is most often used for irrigation, especially for growing wheat & during the monsoon season (July to October with abundant rainfall), the demand for rice is met by the combination of monsoon rains and groundwater that transfers excess nitrate to shallow aquifers through vertical connections. This can cause secondary reactions in aquifer minerals, leading to the mobilization of toxic pollutants, thereby affecting human health. Other sources of groundwater contamination include unrestricted discharge of partially or untreated sewage and industrial wastewater into surface waters, which eventually percolate underground and contaminate surface aquifers.

Introduction

Nitrate contamination is an escalating concern in India, endangering groundwater safety and public health. Groundwater serves as the primary drinking water source for 85 % of India's rural population and fulfills 60 % of its agricultural water demands. The Ganga alluvial plain hosts a significant population, around 10% of the global populace, with agriculture serving as the primary livelihood in the Mid-Gangetic Plain. (World Bank, 2011) Due to over-exploitation of groundwater for irrigation and instability over time, groundwater levels are currently decreasing, especially in southern Bihar districts (i.e. Buxar, Bhojpur, Rohtas, Kaimur, Aurangabad, Gaya, Arwal, Nawada, Jamui, Banka, Sheikhpura and Lakhisarai). Furthermore, the main factor influencing changes in groundwater storage in the Mid-Gangetic Plain is pumping rather than differences in rainfall. Similar alluvial aquifer systems worldwide have faced water table declines due to unchecked groundwater extraction (Konikow, Kendy et al., 2005; Gautam et al., 2020). Furthermore, the swift pace of urbanization and industrialization poses a major threat, deteriorating both the quantity and quality of groundwater (Nijesh et al., 2021; Pant et al., 2021).

High levels of groundwater nitrate primarily stem from extensive nitrogen fertilizer usage, yet other contributing factors include intrinsic elements like geology, hydrogeology, hydro-geochemistry, biogeochemical processes, as well as external human-driven influences such as land use. These aspects collectively affect the leaching and distribution of nitrate in groundwater. In the last 30 years, northern India has experienced declining water tables due to shifting rainfall patterns and extensive groundwater extraction. While this issue receives considerable attention, the deterioration of groundwater quality from significant pollutants like nitrate, arsenic, heavy metals and organic contaminants is equally concerning, albeit less highlighted. (MacDonald et al., 2016). To solve this problem, the Indian government has proposed to increase the efficiency of groundwater use for irrigation by 20% (MOWR, 2014). A recent study supports this suggestion, showing that different watering methods (sprinkler, drip, and alternating wet/dry systems) can increase efficiency by 23 to 49% without reduces productivity (Bouman et al., 2001) but currently, the impact of this proposed improvement on water levels in the area has not yet been quantitatively assessed. Therefore, consistent and methodical monitoring of groundwater quality is crucial to track contamination factors and develop sustainable aquifer management strategies. (Bonsor et al., 2017). Hence, it's crucial to pay particular attention to shallow groundwater extensively used for household needs.

Objectives

(1) To determine the groundwater quality in the Mid-Gangetic Plain and assessing its adequacy for municipal water supply requirements using the WAWQI (Water Quality Index); and

(2) Moreover, to examine the true costs associated with nitrate pollution in the research region in order to determine which organizations bear these costs and who benefits from this circumstance.

Study Region

The current research area is 99,058 square kilometers, including the latitudes of 24°00′N to 28°40′N and the longitudes of 78°40′E to 86°10′E. It is located in India's Middle Ganga Basin includes 29 districts in the state of Uttar Pradesh. This area is located in an active tectonic zone in the Ganga Plain. The majority of the sediments in this basin are from the Himalayas, which are periodically subject to tectonic movements and climate changes. (Shukla, Raju et al. 2008). Over 30% of India's groundwater supplies are unsuitable for human consumption (Cronin, Prakash et al. 2014). It could be a difficult and nerve-wracking effort to provide drinking water to approximately 700 million rural Indians who live in 15 different ecological regions. Additionally, water-related chronic diseases impact the economy and cost the country approximately 180 million working days annually. (Water Aid, 2007). According to the Agency for Toxic Substances and Disease Registry (ATSDR) of 2011, the toxicity ranking nitrate is 220 but this groundwater contamination challenge impact socioeconomically deprived rural inhabitants in India, where about 80% of the population resides. The concentrations of nitrate in drinking water, primarily induced by agricultural activities, exceeded the Bureau of Indian Standards (BIS) of 45mg/L in 11 states of India. The first reported case of high concentrations of nitrate was in the southern district Rohtas of Bihar. (Ray, et al., 2000) Later, groundwater nitrate contamination greater than the BIS standard was reported in a total of 266 and 503 blocks (out of 534) in 9 districts (out of 38) respectively. (Mishra, Shaw et al. 2009). In the consecutive years numerous habitations were found contaminated with nitrate levels greater than the World Health Organization (WHO) standard of 50mg/L. Elevated levels of nitrate in the soil and in the food chain, and health risks associated with the consumption of nitrate through water and foods were also reported in the state. (Singh, Ghosh et al. 2014)

Database and Methodology

Groundwater samples were collected from across the Gangetic plain during the post-monsoon period of 2015 by the Central Ground Water Board (CGWB). They mainly collected samples from hand pumps that draw water from the aquifer. Various factors influencing the chemical composition of water have been extensively studied worldwide using statistical techniques such as hydro chemical scatter plots, simple linear regression, analytical multivariate trilinear regression, multivariate statistical analysis (MSA), remote sensing and geospatial methods. Multivariate statistical analysis (MSA) was used for sedimentary rock aquifers in Canada to understand hydrogeochemical evolution (Cloutier et al. 2008), similar method for assessing aquifer connectivity and sediment flux in Australia (King et al. 2014). In the Ganga basin, researchers have successfully studied the geochemical processes in aquifer evolution and hydro geochemistry using MSA, various graphs and correlation matrices (Pant et al., 2021; Kumar et al., 2021). Geospatial techniques are valuable for spatial visualization and temporary and have been used worldwide to identify potential groundwater areas, understand seasonal variations in contaminants in different hydro geological environments and more. (Nitesh et al., 2021) Maps created with Adobe Photoshop 7.0 taking into account the ATSDR (2011) toxicity level of the contaminant, based on district-level groundwater pollution data for nitrate, fluoride and any other contaminant which we obtained from the official website of Ministry of Drinking Water and Sanitation, Government of India.

Results and Discussion

In Bihar, out of 532 community blocks, roughly 13% of the blocks had nitrate contamination; no district had 100% nitrate contamination. Of the districts in the state, only 4 had nitrate contamination levels of ≥50%, while eleven were completely free of nitrate pollution. A total of 180 community blocks (out of 532) had only one contaminant, according to several groundwater contamination analyses. That is, nitrate contamination affected 8 neighborhood blocks across 6 districts. There were 13 blocks containing iron and nitrate in 8 districts; 5 blocks containing nitrate and arsenic in 4 districts; and 1 block containing fecal coliform and nitrate in just one district (**Fig. 1**). Thus, it determined that four districts are at the extreme end of the pollution prevention scale, and nine districts are at the high priority level, requiring rapid attention to water management. Most of the districts that border the Ganges River are classified as either high priority areas or extreme areas. Groundwater mitigation strategies and interventions should be given top attention in the

districts of E. Champaran, Samastipur, Vaishali, and Kaimur. The current study examined the following research gaps and insights in light of the findings:

(1) Lack of guidelines for the minimum number of drinking water sources (sampling density) in a community and inaccurate data on the pollutants that are specific to a community's water quality.

(2) The inability to prioritize mitigation plans due to a lack of instruments for decision-making resulted in the failure of water management programs.

(3) The monitoring of water quality and mitigation strategies is increased when sampling density criteria, or the minimum number of samples to be evaluated per square mile, are not followed.

(4) Many water filters were created and tested on a national and regional level in the areas affected by multiple contamination; however, the majority of the time the filters failed.

Magic Limit of Nitrate in Drinking Water

What is the safe limit for nitrate contamination to protect public health? The simple answer is that we do not know and can agree with people, who say that the 10 ppm may not be the right number, and that's a completely different discussion as what is the allowable level of nitrate in our water supply, and should we be looking at just the isolation of nitrate alone or should web looking at nitrate in with other compounds such as uranium, fluoride, arsenic or others around?. Another important thing for people to understand that to go based on that 10-ppm number because that's what's legal. It's important to kind of layout where that number comes from (Blue baby syndrome based) decade's worth of health studies and showing the difference between what is legal and what is safe? So presumably that is a good place to start not trying to debate what the magic number is or what should be legal? We do know there is a growing awareness that nitrate contamination is probably associated with a number of public health conditions at levels much lower than the BIS (Bureau of Indian Standards) ISI 201245mg/LNO3-. Conditions are, namely, Colorectal cancer [from0.87 mg/LNO3-N], Abortion [from5.5 mg/L], Premature babies &/or short-term gestation [from5.5 mg/L], Thyroid cancers [from2.5 mg/L], ladder cancer and Spinal bifida, brain tumors and spinal cord defects of babies. (**Fig.** 2)

The Indian Government was and still been failing to put public health before GDP. This is underscored by a "risk analysis" commissioned by CGWB who are

in an illusion that high levels of nitrate contamination in drinking water does not pose a risk to human health so long as yours green. (Anti-oxidants in the diet should provide adequate protection). In the absence of not too many Indian research studies, it is useful to look to first world countries prepared to spend money on much needed research.

Who is Receiving the Benefits for Nitrate Contamination?

The question of who benefits from purifying the water quickly becomes a delicate question when you consider who benefits from using the nitrates that need to be purified. Obviously, it's the producers/farming community in the area, but it's not just the producers, it's the whole chain that makes money from this grain, whether it's cooperatives, selling seeds or selling chemical ointments. This causes the money chain to spread rapidly. In India, the amount of money paid out by the medical system for nitrogen-related cancers or other water contamination-related health concerns is in the millions of INR, as are the health care costs. Who else stands to gain if we successfully address these issues? The quality healthcare that we provide to the rural population is not just for Bihar, but anything that is designed in this state can be applied to other Indian states as well, where we need to take care of the rural population. You can move to another state. Since the main activity is agriculture, we have developed a system to address these issues. How to effectively care for this population could benefit us and, frankly, other places around the world (**Fig.** 2).

Who is Paying Costs for Nitrate Contamination?

In terms of health impacts, obviously the person who is dealing with the disease, the toxicities that comes with the therapy for it. It also then impacts the rest of their life because even though the person who survived the disease, 75% of them will go on to have long term impacts of the care that they received that will require medical attention for the rest of their life. According to a 2015 research report by Gahlot & Kumar, patient registration data comes from Mahavir Cancer Sansthan Hospital in Patna (Bihar) India, shows that the annual registered new patients from all cancers were 20,746 and 50% of the patients belong to 6 districts (Bhojpur, Saran, Muzaffapur, Samastipur, Vaishali & Patna) which fall in Gangetic belt. The study found that 95% of patients were of low socio-economic status and 54% of patients had never attended school. Furthermore, groundwater contamination, poverty, and disease literacy were identified as key important factors for the high incidence of cervical cancer. Who else pays that cost? The family in many different

ways, first of all, obviously the horror of dealing with a child/person who has cancer or others health issues, but in that bill logistics terms, we know that there are many, many costs that are passed on to the family. Whether that is the idea of can they stay employed because it takes so much time off to care for their child both in land outside of the hospital, travel costs that can be impacted more on rural areas for people have to travel such a great distance. So if we say that water quality is having a hand in diseases like cancer or birth defects, the cost is going on to the family Source: MCS (Mahavir Cancer Sansthan), Registration Data 2015, Patna (Bihar). Besides that; when it comes to discussing contamination or setting regulations or policies, or even just changing the practices. The discussion always comes down to cost benefit, and it's much easier to come up with figures for additional treatment at a water treatment plan to or cost too businesses or farms for prevention measures, but feel like downstream cost of the health impacts, which is always missed out, because it is harder to quantify it spreads across many individuals instead of just impacting one entity with financial records even and those impacts are harder to relate directly back to the water contamination. So try and bridge that gap between what we know academically from research about health risks, and then what we can do to advance policy discussions and paint those fuller fair pictures of the costs overall, because it's not just treatment plant or cost to businesses, cost of farms, there is also health impacts and all of those other peripheral impacts really needs to be taken into account.

Conclusion

India's food security is largely dependent on its groundwater system in the Indo-Gangetic Basin (India), hence the current over exploitation of this groundwater resource is a serious worry. The presence of higher groundwater nitrate concentrations in predominantly agricultural parts of alluvial IGB basin aquifers, is of grave concern to the region's vast groundwater-dependent population. The groundwater in most parts of Bihar is getting increasingly contaminated with either nitrate or other forms of dangerous pollutants, as demonstrated by early inquiry and data analysis. This is not a legacy issue, but a worsening situation. The majority of the districts bordering the Ganges and its tributaries are classified as either extreme or high priority zones. Because the exposed communities are socio-economically deprived, water filters capable of filtering numerous contaminants should be produced and delivered at a discounted rate to the affected communities. Furthermore, we must emphasis the importance of long-term monitoring research, including modelling approaches, to aid in the development of more detailed quantification of groundwater nitrate

problems and appropriate groundwater management policies, not only in Bihar but across India. We all benefit if we can increase their (farmers') efficiency, reduce their input costs, and keep nitrogen out of the water. This escalating pollution trend requires immediate and drastic solutions to prevent further degradation of natural water bodies, particularly in developing countries like India, where water shortages exacerbate the issue. Urgent actions are essential to avert the complete deterioration of these vital water resources.

IMPACT OF TROPICAL CYCLONE DISASTER ON LIVESTOCK RESOURCES OF ODISHA

Dr. Damodar Panda, Dr. Rashmi Rani Anand and Dr. Maya Devi

Abstract

Odisha located on the eastern coast of India is being frequently affected by cyclonic storms. Life and property are generally affected by storms and floods. The economy of the coastal Odisha is agrarian, people grow crops, keep livestock to utilize crop residues as fodder, utilize natural fertilizer in agriculture, and augment family income. Economically and socially weaker sections of the society exclusively depend on livestock for their livelihood. Most of the people in the coastal Odisha live in traditional temporary houses made up of locally available construction materials not resilient to cyclonic storms and floods. They keep the domesticated animals mostly milching animals, drought animals, goat, sheep, pig and poultry birds in temporary houses. As part of the disaster management policy adopted by the state govt. evacuation of population could minimize human casualty, but no such policy adopted for a long time for livestock, which results injury and death of large number of livestock and poultry birds. Realizing the importance of livestock for the rural economy in the disaster-prone area, state govt. has initiated measures for evacuation of livestock and their care during disaster. In spite of this recent measure still large number of livestock and poultry birds are killed due to the impact of cyclonic disasters. The only solution is the construction of permanent livestock sheds in the coastal villages, awareness generation among the livestock farmers, post disaster care and insurance of the livestock.

Introduction

Disasters affect animals and human beings with more impact on animals. Animals are more vulnerable to disasters than human beings. In the developing countries the impact of disasters on animals is higher and more long lasting than in developed countries (Heath et al 1999).In developing countries livestock employs more people than developed countries (Schwabe 1984). In India, 70% of all livestock

are owned by 67% small and marginal farmers, who depend on animal husbandry for their livelihood. The contribution of animal husbandry to the GDP of India has grown up significantly over the years. Disasters that affect animals can, therefore, reduce an important source of employment, revenue and wealth particularly affecting small, marginal farmers and landless livestock keepers who often solely depend on livestock for their livelihood. In spite of serious implications of natural disasters on livestock and livestock owners, disaster management of livestock has yet to receive attention in India as also many other developing countries of the world (Sen and Chander 2003).The Livestock sector plays a central role in nature resource based livelihood of the vast majority of population and often considered as the poor people's ATM. Apart from providing a subsidiary income, rearing of livestock is a source of nutrition in the form of milk, egg and meat. They are kept as a unit of production and provide an important source of revenue, employment and wealth. This sector is facing problem due to the natural disasters like cyclone and flood. Lack of well-developed disaster management plans results in a severe loss of human life, animal life and property, which could be saved if necessary, mechanisms were evolved. The preparedness, response and rehabilitation mechanisms were primarily focused on human beings, whereas, inadequate attention to livestock management led to heavy losses and delayed recovery from livestock related damages. Whenever any region, country or a place is struck by any natural calamity be it cyclone, flood, earthquake, volcanoes etc. the livestock is first to be affected, the reason being the government's relief and rehabilitation measures are focused primarily on population and therefore the sector gets least importance.

Study Region

Odisha is located on the east coast of India with a coast line of 480 km along the Bay of Bengal. The state has an area of 15,5707 sqkm. and consists of 30 districts. Physiographically the state has been divided in to (i)-the northern plateau, (ii)-the central river basin, (iii)-the eastern hills, and (iv)-the coastal plain. The climate is tropical monsoon. The coastal plain of Odisha is agriculturally developed with high population density. The coastal districts are economically developed in comparison to other parts of the state. The state is vulnerable to multiple disasters. Due to its subtropical coastal location, the state is prone to tropical cyclones, floods, tidal surges and tsunamis. The state accounts for 4.05 % population of livestock in the country. According to 2012 livestock census, total livestock was 207.33 lakh Cattle and buffaloes-59.56%, goat and sheep-38.56%, pigs-1.35%.

Objectives

(1) To study the impact of cyclonic disasters on the livestock resources.

(2) To analyze various measures taken by the govt. and the community to reduce the loss and injury of the livestock.

(3) To analyze the livestock affected and loss in the districts.

(4) Suggestion for various measures to be taken to reduce the impact of cyclonic disasters on livestock resources.

Database and Methodology

Data were collected from memorandum on Cyclones from the Special Relief Commissioner, Govt. of Odisha. Disaster management plan of livestock, Animal Resource Development Sector, Govt. of Odisha, Economic survey of Odisha, review of literature, electronic and print media. Data has been analyzed at district level and presented as graphs to understand the trend of cyclonic disasters affecting livestock and loss. Also analyzed the spatial vulnerability of livestock by composite index.

Impact of Cyclone Disaster on livestock Resources of Odisha

Super Cyclone, 1999

The Super Cyclone of 1999 was the most destructive Cyclonic storm of the century. The most severe Super Cyclonic Storm hit the coast of Odisha near Paradeep on 29th October 1999. It affected severely 12 coastal and adjoining districts with wind speed of 270-300kmph and tidal surge of 5-7 m. height. The disaster management policy of the government was rescue and relief operation. The Cyclone prediction was not accurate in its intensity, wind speed, direction and timing. Warning was received three days before the Super Cyclone. People did not take the warning seriously, thus Resulted heavy human and livestock casualty. Lack of adequate cyclone/flood shelters and the shelters constructed by the red cross society was in damaged condition and few in numbers. Numbers measures were taken for evacuation of livestock to safer places before Super Cyclone. The livestock farmers received the warning through various sources well before (24 h to 12 h) the onset of the Super cyclone but, majority of them could not shift their animals to safe places. Non availability of sufficient safe shelters was the most important problem of shifting livestock, non availability of shifting arrangement, delay in decision making and ambiguity of warning. As a result, the majority of the livestock farmers

only untethered their animals before leaving home to save their own lives. They did not put much value to the warning due to their own judgment about the possible impact of the cyclone since they underestimated the impact. The warning messages could not provide information on the possible magnitude of the damage that the cyclone may cause and that might be the reason, why many of them did not think of an early evacuation. Livestock farmers had to suffer a lot for carcass disposal. Since most of the study area remained flooded by the sea water for about a week or more the farmers could not bury or burn the animal bodies. Later, Non-Governmental Organization (NGO) and Amy personnel took the responsibility but it was after 10 to 15 days of the Super Cyclone. The Veterinary personnel were not involved in the carcass disposal as they had no skills and experience. Marginal and small farmers suffered the most due to loss of livestock in the cyclone since they owned large number of livestock. The loss of farmers could have been reduced significantly had insured their animals. The Super cyclone. brought about major decline in the numbers of cattle, buffalo, sheep and ducks, while goat, pig and poultry only made up the loss quickly but also made impressive gains in their numbers by the year 2001(Kurup 2003).It was also reported that the affected areas were the major producer of milk, meat and eggs (Bhanja etal1999) and severe scarcity of milk and milk products were noticed in the coastal districts of Odisha even after 2 years of the Super cyclone(Das 2002).Government paid compensation of Rs.2420.48 lakh for loss of animals and birds, supply of chicks for immediate recovery programme Rs.322.50lakh,establishment of poultry units for the poor families Rs.938.00 lakh, community fodder cultivation Rs.190.00lakh,growing of perennial trees for fodder Rs.186.00lakh and development of fodder nurseries Rs.13.89lakh.Govt spent Rs.4070.871lakh for livestock due to Super Cyclone impact.

Phailin

The very severe cyclonic storm (VSCS) Phailin hit the southern coast of Odisha at Gopalpur on 12th October 2013 with wind speed of 205-220kmph and tidal surge of 3-3.5 m. height ravaged 14 coastal and adjoining districts of the state. On getting the information from the IMD on 8th October, the state govt. intimated to all the collectors, the print and electronic media. On the 10 of October 2013, the IMD reported that the deep depression had intensified in to a Very Severe Cyclonic Storm named as Phailin, indicating the threat to Odisha coast along with the track and intensity of the system. Accordingly, the collectors of the 14 coastal and adjoining cyclone prone districts were alerted through mailman and telephone. As part of the preparedness measures steps were taken for cattle health and supply of cattle feed

for the affected cattle population. Steps were taken to shift 31,062 livestock to safer places.283 veterinary teams were deployed, 89840 livestock treated, 230400 cattle vaccinated, 849.25 MT of cattle feed distributed among 29248 livestock in 1284 cattle camps. They were directed to take all precautionary/preparatory measures to meet the cyclone threat. Total livestock affected were 4689838 with 3250810 Large livestock and 1439028 small livestock. Poultry bird affected were 2368865. Maximum 1995500 livestock and poultry affected in Ganjam district. Total 4502 livestock lost and maximum 3704 livestock lost in Ganjam district.99159 cow sheds were damaged with maximum 65371 damaged in Ganjam district. As per the relief code provision for the replacement of the animals killed due to Phailin subject to ceiling of 1 large milch animal @Rs.16400 or 4 small milch animal @ Rs.1650 or 1 large drought animal @ Rs.15000 or 2 small drought animals @ Rs.10000 per household. For the reparation of the damaged cowshed @Rs1200 paid. Government spent is Rs.3277.15lakh for the livestock affected by Phailin (**Table-**1and 2, **Fig. 1** and 2).

Hudhud

The Very Severe Cyclonic Storm Hudhud crossed close to the Visakhapatnam coast of Andhra Pradesh on 12 the October 2014 with wind speed of 80-100 kmph. and passed through southern Odisha. IMD, Pune disseminated alert of the affected districts of Odisha from 9thOctober on wards. The state govt. circulated the IMD forecast to the Collectors of 16 coastal and adjoining districts likely to be affected, with instructions to remain in full preparedness to meet any eventuality. Collectors of 8 southern districts were cautioned about the flash flood and instructions were issued to start evacuation of livestock and domesticated animals to safer places before the occurrence of the disaster. Advance arrangements were made for the cattle health care and supply of cattle feed in the affected districts. As preventive measure 22 297 animals were shifted to safer place,106 veterinary doctors and 680 para- veterinary teams were deployed,3140 livestock treated,26950 cattle vaccinated and 159 MT of cattle feed distributed. Large areas were inundated in Kendra pada and Puri districts due to storm surge.15 districts affected due to the disaster. Due to its impact 39350 livestock and poultry affected. 670 livestock killed in 4 districts, Gajapati, Koraput, Malkangiri and Rayagada. Maximum 614 livestock killed in Koraput district.670 big animals,198 small animals and 472 poultry birds killed. About 57 cattle sheds damaged. As part of the compensation and related expenditure, the state govt. spent Rs.5.35lakh for the disposal of caracasses, Rs.41.78 lakh for the replacement of livestock, Rs.30.41 lakh for the distribution of

fodder and Rs.85,500 for the reparation of cattle shed. Government spent Rs.78.67 lakh. For the livestock affected by Hudhud.

Titli

The Very Severe Cyclonic Storm Titli crossed the coast near Palasa of Andhra Pradesh, south west of Gopalpur with wind speed of 140-150 kmph. and tidal surge of 1meter on 11th October 2018. The Indian Meteorological Department (IMD) reported on 7th October 2018 about formation of a low-pressure area over south east of Bay of Bengal and adjoining North Adaman Sea. It was predicted that the depression very likely to move towards Odisha during the next 72 hours. After getting the information from the IMD, the state govt. started closely monitoring the situation and intimated all the Collectors, print and electronic media. In the preparedness measures, all Collectors of likely affected districts were instructed for the evacuation of livestock and domestic animals to safer places and to ensure that no cattle should be left tied in kutcha (temporary)house. All cyclone bulletins and warnings shared by the IMD disseminated through DD, AIR, other electronic media for information of the public. 711 MT cattle feed supplied,208462 animal vaccinated,129637 animal treated,158 veterinary team deployed,1798 veterinary camp opened and 48858 carcasses disposed. Livestock were affected in six districts, Cuttack, Gajapati, Ganjam, Puri, Kandhamal and Rayagad. Total 481068 livestock affected with large animal 299795 and small animal 181273.Total poultry affected were 481068.Maximum number of 190349 livestock affected in Ganjam and Gajapati districts of south Odisha. Government spent Rs.623.58lakh.for livestock affected by Titli.

Fani

Extremely Severe Cyclonic Storm Fani crossed the Odisha Coast between Satapada and Puri on 3rd May 2019 with wind speed of 175-185kmph. and tidal surge of 1.5-meter height. On 28th April, IMD Indicated that cyclonic storm Fani moved northwards and would very likely to intensify in to a very severe cyclonic storm. There was also forecast and warnings for Odisha that light to heavy rainfall likely to occur at one or two places in southern Odisha on 2nd May and heavy rainfall from 3rd May over coastal Odisha. Though there was no warning issued by IMD for the Odisha coast, the state government started closely monitoring the situation. On 30th April IMD reported that the Very Severe Cyclonic Storm Fani very likely to cross Odisha coast between Gopalpur and Chandbali to the south of Puri on 3rd May afternoon. Massive preparedness measures were undertaken by

the government soon after receipt of warning from IMD. The districts were alerted based on the probable cyclone track and impact area.14 coastal and adjoining districts were affected due to the impact of Fani. Severely affected districts are Puri, Khurdah, Ganjam, Kendrapara, Cuttack and Jajpur. The cattle population shifted to safer places and cattle feed /fodder arrangement was made. Instructions were issued to field veterinarians to aware dairy farmers and small animal owners to take immediate measures by shifting their animals to safe places to avoid livestock loss.635 animal shelters in school premises and multipurpose cyclone shelters were identified. Over 40,000 large animals like cow, buffalo, bullock etc. were shifted to such shelters.300MT cattle feed stored to meet the requirement. About 80,000 livestock farmers of such districts were made aware about safeguarding of animals and severity of the cyclone through sending of mobile voice messages under mobile advisory programme. Steps were taken for health care services and carcass disposal. Total livestock affected were 3439282,large animal affected were 2443329 and small animal affected were 996053.Poultry bird affected were 5371373.Maximum livestock and poultry affected in Puri, Cuttack and Khurdah districts. Total 6281 livestock lost, maximum loss in Khurdah, Puri and Cuttack districts.119694 cowshed damaged. 2006.5 MT of cattle feed were supplied and steps were taken for the supply of two thousand quintals of green fodder to the severely affected districts. Mobile veterinary units and 115 rapid response teams were used for conducting veterinary camps,4105 animal health camps organized and 5.08 lakh animals treated. Compensation given for the loss of livestock for the replacement of drought/milch animals Rs.950.92lakh,provision of fodder and cattle health care Rs.2432.85 lakh, disposal of carcass RS.437.56 lakh and reparation of cowshed Rs. 2513.574 lakh. Govt. spent Rs6334. 904.lakh for livestock affected by Cyclone Fani.

Bulbul

Very Severe Cyclonic Storm Bulbul crossed Sunderban delta on 9th November 2019 with wind speed of 110-120 kmph. and tidal surge of 0.5-1.0 m. height. On 5th November IMD informed that the depression would very likely to intensify in to a deep depression and cyclonic storm. It would very likely to move towards Odisha-West Bengal coast. Soon after receiving the meteorological warning, the state govt. started closely monitoring the situation. As per the special bulletin of IMD on 7th November the cyclonic storm Bulbul very likely to intensify in to severe cyclonic storm and move towards West Bengal–Bangladesh Coast. Soon after receipt of warning from IMD, the state govt. took all required preparedness

measures to combat the possible situation. It affected 6 coastal and adjoining districts of north Odisha. Due to its impact 31238 livestock affected with 27344 large animal and 3894 small animal. 6125 poultry affected. Only two districts, Bhadrak and Kendrapara livestock were affected and maximum affected in Kendrapara district. Total 19 livestock killed, 1464 cowshed damaged and maximum damage in Kendrapara district. 312 animal health camps at every affected GPs organized. Compensation given for replacement of milch/drought animal of Rs.4.00 lakh, animal health camps Rs15.60 lakh, reparation of cowshed Rs30.74 lank. Govt. spent Rs.50.34lakh for livestock affected.

Amphan

The Extremely Severe Cyclonic Storm Amphan crossed West Bengal coast of Sundarbans on 20th May 2020 with wind speed of 155-165kmph. and tidal surge of 4-5 m height. On 16th May, the IMD informed that the low pressure area would very likely to intensify in to severe cyclonic storm likely to move towards West Bengal Coast during 18th to 19th May 2020. The coastal Odisha would likely to experience light to heavy rainfall from 18th to 20th May.IMD informed that It was associated with high wind speed and heavy rainfall. As part of the preparedness measure, the government alerted the collectors of the 12 coastal and adjoining districts to effectively handle the disaster. Awareness campaign on protection of animal resources from possible cyclone situation was launched in electronic as well as print media. People were advised to shelter the cattle and domestic animals at safe places. They were advised to evacuate their cattle to the ground floor of the Multipurpose Cyclone Selter/Multipurpose Flood Shelter (MCS/MFS) and other suitable buildings in case of necessity. It affected 10 coastal and adjoining districts. Total 1903 livestock affected with 1249 large animal and 654 small animals. 18875 poultry affected. Livestock affected in 6 districts with maximum in Jajpur district.38 livestock killed with maximum in Keonjhar district.393 cowshed damaged. As part of the compensation Rs.8.20 lakh spent for replacement of drought and milch animal and reparation of cow shed Rs.8. 25 lakhs. Government spend Rs.16.45 lakh for livestock affected by Amphan.

Yaas

Very Severe Cyclonic Storm Yaas crossed north Odisha coast south of Balasore with wind speed of 130-140 kmph. and tidal surge of 2-3m.height on 26th May 2021.Indian Meteorological department (IMD) reported on 20th may 2021 that a low pressure area would very likely to form over north Andaman sea and adjacent

east central Bay of Bengal around 22nd May 2021.it would very likely to intensify in to a cyclonic storm and reach Odisha-West Bengal coasts around 26th May morning. Soon after receiving the meteorological warning, the state government started closely monitoring the situation. As part of the preparedness measure IMD weather bulletin and cyclone warnings were disseminated to Collectors, departments and other stake holders at regular intervals. The livestock and domesticated animals of vulnerable area were shifted to safer places. No cattle let tied in kutcha house. People were advised to shelter the cattle and domestic animals at safe places. They were advised to evacuate their cattle to the ground floor of the MCS/MFS and other suitable buildings in case of necessity. Required vaccines, essential medicines were prepositioned at veterinary hospitals/dispensary and 1500 MT of cattle feed was kept ready by OMFED. Due to its impact 11 districts were affected. Total 1358578 livestock affected with 1022361 large animals and 336217 small animals. 1115810 poultry affected. 72 livestock killed.3024 cowshed damaged with maximum damage in Bhadrak District.75 mobile veterinary teams deployed, 37 animal health camps organized, 1617 animals treated and 5100 animals vaccinated. Compensation paid for replacement of milch/ drought animals Rs.16.684 lakh and cattle feed Rs.148.760 lakhs. Government spent Rs.165.444 lakh for livestock affected by Yaas.

Livestock Affected and Loss in Districts

On the basis of the recent past cyclonic disasters affected Odisha from 1999 to 2021, total livestock and poultry affected in the state was 191,64, 505.Livestock affected was 100,01,907 and poultry affected 91,62, 598. Large animal affected were 70,44,888 and small animal 29,57,119. Maximum livestock 46,89,838 affected by Phailin followed by Fani and Yaas. Least affected by Amphan 1903.Maximum poultry 53,71,373 affected by Fani followed by Phailin (Table.1 &**Fig. 1** & 3). The most vulnerable district is Puri with maximum 3618558 livestock affected and lowest vulnerable district is Dhenkanal with 3011 livestock affected. On the basis of the composite index, very high vulnerable districts are Cuttack, Ganjam and Puri, high vulnerable are Bhadrak, Jagatsinghpur, Jajpur, Nayagarh and Kendrapara, medium vulnerable are Balasore, Mayurabhanj Khurdah, Keonjhar and Gajapati low vulnerable are Dhenkanal, Kandhamal and Rayagada. The vulnerability depends on the number of livestock farmers, intensity and track of the cyclone over the state. The vulnerability of the livestock is gradually declining as the people are more aware, construction of more permanent cowsheds and alternate shelters for the livestock during cyclones (**Table-**1 and **Fig. 1** and **Table-**2)

Livestock loss

Loss of livestock and poultry are due to the impact of very high wind speed coupled with flood and damage of temporary structures. Total livestock lost was 456110 with maximum livestock lost due to Super Cyclone 1999 was 621377. Lowest number of livestock lost was 19 by Bulbul. After Super Cyclone of 1999, loss of livestock drastically reduced to maximum 6281 by Fani in 2019.After Super Cyclone loss of livestock reduced to only 16388 from 2013 to 2021 by six cyclonic storms. Maximum livestock lost 110742 in Jagatsinghpur district, the landfall point of Super cyclone and minimum 10 in Rayagada district of southern Odisha. The composite index shows very high loss of livestock in Cuttack, Jagatsinghpur and Kendrapara districts, High loss of livestock in Balasore, Bhadrak, Jajpur, Dhenkanal, Puri and Khurdha districts.

Table-1: Livestock Affected by Cyclone Disasters in Odisha

Sl. No.	Districts	Cyclone						Total
		Phailin	Titli	Fani	Bulbul	Amphan	Yaas

Management of the impact of cyclone disaster on livestock population

The new disaster management plan incorporates provision for evacuation of livestock and provision of fodder, drinking water and medicine. As preventive measures mobile veterinary team deployed, animal health camps organized, affected animals treated and vaccinated. In Super Cyclone of 1999, the number of livestock evacuated is still very low in comparison to the number of livestock in highly vulnerable areas. Evacuated livestock were kept in flood/cyclone shelters and school premises identified by the district administration for the purpose. People are also asked to take the animals to safer places and don't tide them in cowshed. Developed cyclone prediction, early warning and awareness of the people could able to reduce the loss of livestock. Large number of large and small livestock are affected

due to the temporary cowsheds damage by wind and flood water. Loss of livestock is gradually decreasing where as number of livestock affected are increasing. Death of poultry bird is always high due to high wind speed; adequate protection needs to be taken. Post cyclone storm care of the livestock taken including immunization and fodder supply. Community based organizations lacked the necessary trained manpower, resources and know-how to cope with the challenges. In the aftermath of the cyclone, feed and fodder were scarce and consequently many animals starved and the productivity of animals decreased. The various steps to be taken prior, during and after disaster in relation to livestock management includes: Prevention: a) construction of shelter for animals in cyclone and flood prone areas and in case of shifting animals to safer places preference should be given to bullocks, milk cows, breeding bulls as their loss can cause immense damage to economy. b) Untethering the animals when shelter is not available c) Efforts should be made to collect feed, fodder, medicine etc and they should be kept at safer places d) Proper training should be given to farmers for evacuating their animals. Relief: a) Proper care should be taken to protect the animals against prey, poisonous snakes and reptiles b) proper arrangement for quick movement of veterinary personals to reach animals for treatment, vaccination and deworming. Rehabilitation: a) Livestock owners should be provided with compensation in case of livestock loss or diseased condition b) Working bullocks and milch animals should be provided from other unaffected regions that are surplus in these animals c) Reconstruction of veterinary and A.I centers that are damaged due to floods d) A permanent feed security system should be set up in flood prone areas) Livestock owners must insure their livestock. The scarcity of feed and fodder after any disaster poses a serious and indirect threat to the livestock. The use of urea treated straw as a feeding option that has the potential of meeting up the challenge to some extent. The straw feeding during the disasters can reduce the burden on the already scarce feed resources without compromising the production performance and also suggested use of Urea Molasses Mineral Block (UMMB) as a viable feeding option during disasters. Further, by products of sugarcane like bagasse, molasses, sugarcane tops etc., should be fed to animals during scarcity period. They also reported that urea when used for treatment of bagasse enhances its nutritional quality and steam treatment can also be used to increase its digestibility.

Conclusion

Exposure to cyclonic disasters and their consequences play a significant role to the socio-economy of the coastal Odisha. Livestock support the livelihood of

majority of the people of this region. Livestock are the easy victim of the cyclonic disasters as people keep them in highly vulnerable temporary cowshed. Protection of livestock resources should be given top priority for livelihood support of the poor people of the coastal villages. The number of livestock loss has been reduced due to preventive measures taken by the government but adverse impact on livestock is increasing. After disaster fodder problem becomes critical as dodder damaged by flooding water. Steps must be taken for availability of cheap fodder for the livestock. The number of poultry loss is increasing as the birds are sensitive to high wind speed. Number of livestock affected due to temporary cow sheds are increasing though the loss is reducing. Inadequate shelters for the livestock increase vulnerability. Steps must be taken to reduce death of livestock by construction of permanent cowshed. Compensation given for the loss of livestock and poultry ceiling must be removed by fully compensation by alternate agency. All livestock owners must insure their livestock for their benefit. Livestock farmers severely affected by loss of livestock should be provided alternate livelihood support.

SPATIO-TEMPORAL VARIATIONS OF AGRICULTURAL LABOR WAGES IN INDIA

Professor Upma Chaturvedi and Abhinav Singh Yadav

Abstract

The paper analyzed variations in agricultural labors' real wage in 19 states of India from 2005-06 to 2020-21using statistical methods. For a comprehensive study and analysis of the changes in agricultural labour wages across the country, the paper attempted three statistical methods viz comparative analysis of agricultural wages' means across the time period; measuring fluctuations in the change in wages via coefficient of variance; and compound annual growth rate of agricultural wages. Mean real wages of Indian states across the years shows that, Southern and North Western states have higher wages as compared to states in Great Northern Plains, North East India and Central Uplands. Some states have deviated from general trend of increase in wages with the increase in economic growth and development. This decline in wages occurred both in states observing high and low agricultural wages. This anomaly emerged as a national concern because of its spatial diversity across the country and raising frequency in recent years. Fluctuations in the real wages of agricultural labor of different states across the years have no relation with actual real agricultural labor wages of the state. Both states with high and low wage rates experienced high as well as low fluctuations also. Growth rate of agricultural labor wages showed an inverse relationship with the past's real wage rates, that is, states which had high wage rates in past have showed relatively slower growth as compared to those states that had low wage rates. Agricultural labor real wages' increment requires special attention by the policy makers and administrator as it plays major role in boosting rural economy by raising demand of goods and services that too by masses, increasing production process conferring more diverse employment opportunities to disguised unemployed individuals, adding family income and improving standard of living by boosting education and health.

Introduction

A person is treated as an agricultural labor, if he/she follows one or more of the following agricultural occupations in the capacity of a labor on hire, whether paid in cash or kind or partly in cash and partly in kind: farming including cultivation, growing and harvesting of any agricultural commodity; production, cultivation, growing and harvesting of any horticultural commodity; dairy farming; raising of livestock, bee-keeping or poultry farming; and any practice performed on a farm as incidental to or in conjunction with the farm operations (including any forestry or timbering operations and the preparation for market and delivery to storage or to market or to carriage for transportation of farm products). Most deprived section of rural India is landless families who either migrate toward cities or work as agricultural labor. Agricultural workers constitute the most neglected class in Indian rural structure. Agricultural laborer's households constitute the historically deprived social groups, displaced handicraftsmen and dispossessed peasantry. Since, they possess no skill or training, they have no alternative employment opportunities either. Agricultural labors are socially and economically poorest section of the society. They are the poorest of the poor in rural India. The reason for their poverty is their easy exploitation because they remain largely unorganized, therefore their level of income, standard of living and the rate of wages have remained abnormally low. Demand of agricultural labor has declined due to improved farming methods and mechanization of middle and rich farmer's fields, decline in demand and abundance of supply pulled down the wages of the laborers making them economically further more weak. Agriculture laborer wages are function of demand supply of labor, irrigation and cropping intensity of region, fixed minimum wages, price of farm output in the market determining the paying ability of the employer, cost of living etc. Therefore, agriculture laborer wages are different in different states.

Study Region

The study is based over 19 states of the country including Andhra Pradesh, Assam, Bihar, Gujarat, Haryana, Himachal Pradesh, Jammu & Kashmir, Karnataka, Kerala, Madhya Pradesh, Maharashtra, Meghalaya, Odisha, Punjab, Rajasthan, Tamil Nadu, Tripura, Uttar Pradesh, and West Bengal. Data of CPI-AL base year 1986-87 is in continuity and gives data of parent and child state data on the name of the parent state to sustain continuity in the data, For example, Chhattisgarh from Madhya Pradesh, Jharkhand from Bihar, Uttarakhand from Uttar Pradesh, and Telangana from Andhra Pradesh. Therefore, these states are not studied separately rather they are clubbed with the parent states.

Objectives

The objective the paper is to analyze spatio-temporal variation of agriculture labor real wages across different states of India, finding out fluctuations in trend of increase in agricultural wages and evaluating growth rate of increase in agricultural wages in India.

Database and Methodology

Secondary data of nominal wages of agricultural laborers of different states used in the paper is extracted from Labor Bureau Shimla, Ministry of Labor and Employment, Government of India for 2005-06 to 2020-21. Consumer Price Index Agricultural Labor data for the same time period is taken from Handbook of Statistics on Indian States, RBI and Labor Bureau Shimla. State Indices:

$$I_n = \frac{\sum P_n Q_0}{\sum P_0 Q_0}$$

Whereas: I_n= Index Numbers

P_n= Price of current period

P_o = Price of base

Q_o = Quantity of base year

All-India Index: The all-India index is worked out as a weighted average of the indices of 20 States, weights being the estimated consumption expenditure of all rural and agricultural labor households in each State as a proportion of corresponding expenditure for all-India. All-India group indices are also compiled by using the State weights in the particular group, derived as a proportion of corresponding expenditure at all-India level. Base year of CPI is adjusted to 2014-15 for whole data set using following formula:

$$\frac{x}{CPI(214-15)} \times 100$$

x = CPI (2005-06 to 2020-21)

In the study real wages are used instead of nominal wages which is calculated using following formula:

$$Rw = \frac{Nw}{CPI} \times 100$$

Whereas: Rw = Real wage

Nw = Nominal Wage

CPI = Consumer price Index (Agricultural laborers)

Coefficient of Variance is used to measure the fluctuations in the wages of different states. Following formula is used in the study to find out growth rate of agricultural wages along with compound annual growth rate:

$$GR = \frac{PRw \quad CRw}{PRw} \times 100$$

Whereas: GR = Growth Rate

PRw = Previous Year Wages (average of 2005-06 to 2007-08)

CRw = Current Year Wages (average of 2018-19 to 2020-21)

Result and Discussion

Spatio-temporal Variation in Agricultural L labourer Real Wages

Average of 16 years (2005-06 to 2020-21) real agricultural labor real wages in India shows that 8 out of 19 states (Kerala, Jammu and Kashmir, Haryana, Himachal Pradesh, Punjab, Tamil Nadu, Tripura and Rajasthan) showed higher wages than national average with exceptionally high wages in Kerala followed by Jammu and Kashmir while the minimum wages are being paid in Madhya Pradesh followed by Maharashtra, Odisha, and Gujarat. Kerala labors are paid high wages due to high demand and low supply of labors. Kerala labors tends to migrate to foreign countries for grasping better opportunities in the form of high wages, better and safe working conditions facilitated by premigration established linkages. Cost of living in Kerala is also high therefore labor wage is highest among all states. Demand of labors in Jammu and Kashmir is not fulfilled as migrants avoid to migrate there because of volatile law and order conditions along with harsh climate and topography. Thus, leaving only local labors in the market for work that too for shorter period of time allowed by climate for cultivation. Himachal Pradesh is known for out migration. Many villages in Himachal Pradesh had turned into ghost villages because of migration by nearly all families out of their village. This trend of migration by youth causes lack of labors in the state. Demand of labors had increased due to rise in horticulture, evolution of modern technology to practice farming at mountains, and improved marketing facility in the form of better roads, and enhanced communication facility. High demand and low supply of labor made

the agricultural wages of Himachal Pradesh high. Haryana and Punjab are hub of highly intensive agriculture which needs capital, technology and labors in large quantity. States themselves are not capable to fulfilled labor demand therefore in-migration of agricultural labors from low wages states like Uttar Pradesh and Bihar is observed in Punjab and Haryana. Only significantly high wages could attract labors to work far from their local area, thus they are offered higher wages. Along with agriculture, Haryana and Punjab have good level of industrialization which creates parallel demand of semi-skilled and non-skilled labors benefiting labors in the form of high wages at both places. Haryana is bordered with national capital which offers huge employment opportunities in tertiary sector, offering opportunities of wages in agriculture sector. Madhya Pradesh and Odisha have high tribal population that migrate and to labors to shift towards tertiary sector. This again push towards increment work as agricultural labor at a very low cost. Their bargaining power is low and their migration also results into adequate supply of labor in the market. Per capita income of farmers is also very low in these states and farmers practicing commercial agriculture are very less, thus these state experience low wage rates. Odisha is one the major rice producing states of India with limited mechanization of agriculture thus leaving large scope for labors to get engaged. Despite state's large share of rice production very meagre amount is cultivated for commercial purpose and mostly done for domestic or self-consumption which don not allow farmer to hire labor on high wages. Family members themselves cultivate in spite of hiring labor. Maharashtra and Gujarat are also among those states that receive maximum number of in-migrants thus they ensure supply in the market. Maharashtra is the state with very high farmers in distress making the state topper in farmer's suicide. The farmers of the state use minimum inputs for the agricultural production. Labor being a factor of production is avoided by the farmers up to possible limits. Uttar Pradesh and Bihar have huge human resource having low per capita income with suitable geographical conditions for cultivation and irrigation source in the form of rivers, canals and underground water. Bihar lags behind in development of other sectors of economy viz secondary and tertiary, which leaves little room for workers to find employment elsewhere, thus there is excessive supply of labors in the market with demand at fewer location causing fall of their wages. Due to high population in both of the states, agricultural land suffered from fragmentation in large scale, making the land unsuitable for commercial crop and fit only for subsistence agriculture which do not support high agricultural labor wages (**Fig. 1**)

Generally, it has been observed that with the economic growth, wages of employees of every sector (including agriculture) increase, but this is not universally applicable. For example, in Gujarat agricultural real wages had declined in 2017-21 period as compared to 2005-09. In many other states also during same time frame, agricultural real wages have seen decline instead of rise. For example, in Himachal Pradesh, Kerala and West Bengal wages declined in 2009-13 from 2005-09. Andhra Pradesh, Punjab and Tripura have seen higher wages in 2009-13 period as compared to 2013-17. Mean data shows that 7 states have witnessed decline in real wages in 2017- 21 as compared to 2013-17 viz Assam, Haryana, Jammu and Kashmir, Meghalaya, Punjab, Rajasthan and Tamil Nadu. Further analysis used 2017-18 as watershed and taking average of 3 year before and after that time period to find out the recent trend of the change in wages of agricultural labor in the country. Out of 19 states, 11 shows that a declining trend of real agricultural wages. They include Assam, Gujarat, Haryana, Jammu and Kashmir, Kerala, Maharashtra, Meghalaya, Odisha, Punjab, Rajasthan and Tamil Nadu. Although pan India data shows increase in real agricultural wages but that is very minute. State irrespective of the actual wages showed declining trend for example, Kerala, the highest paying state and Gujarat second lowest agricultural wages both showed decline in wages. Most significant decline is showed by Tamil Nadu (5.21%), Meghalaya (11.48%), Jammu and Kashmir (5.06%) and Rajasthan (-6.31%). All the states are located at four corners of the country which indicates that the decline in wages in not a regional issue rather a matter of national concern. Making 2014-15 as the divide line for comparison of previous and current agricultural wage we found that most of the states have improved their agricultural wages except for Gujarat and Tripura. Looking at the comparison of before and after 2014-15 collectively with the average of 2015-16 to 2017-18 and 2018-19 to 2020-21 reveals that the initially wages in most of the states were growing but decline of wages witnessed is a problem originated in very recent times that is after 2017.

Fluctuations in Real Agricultural Wages

Fluctuations in wages means abnormal rise and fall of wages. Fluctuation of wages are unsuitable for agricultural labors' sustained growth in a planned way. High fluctuations in wages demotivates labor to continue with the profession and seeks to engage in another alternative work for stable income. Fluctuation of wages may be caused by natural disaster, interference by administration in wage related issue, MSP hike in any specific crop etc. Coefficient of variance used to find the

fluctuations showed that maximum fluctuation of wages is in Odisha, Maharashtra, Tamil Nadu, and Himachal Pradesh whereas Jammu and Kashmir, Kerala, Gujarat, and Meghalaya are states with minimum fluctuation that is have high stability in wages of agricultural labors. Fluctuations in agricultural wages are independent of the level of wages in the states. States with high wages, shows both high fluctuations and low fluctuations in wages, for example Kerala and Jammu and Kashmir, are low fluctuating states whereas Himachal Pradesh is high fluctuating state. Similarly states with low wage rates also lies in both high and low fluctuating category. For example, Gujarat is low fluctuating state and Odisha is highest wage fluctuating state whereas both have low agricultural wage rates.

Growth Rate of Agricultural Wages in India.

Growth rate of agricultural wages is calculated between 2005-06 and 2020-21 using three years average (2005-06 to 2007-08) as previous data and three years recent data for current entry. Highest growth rate is observed by Odisha followed by Tamil Nadu, Bihar, and Uttar Pradesh whereas lowest is observed by Gujarat followed by Meghalaya, Tripura, and Jammu and Kashmir. These four states have showed negative growth rate, that is the wages in the 2005-06 were more than the 2020-21. This is because of sudden decline in agricultural wages due to economic impact of COVID-19. Despite fall in wages in current year due to COVID-19, 15 showed positive growth rate, indicating the overall growth in the wages. Compound annual growth rate for analysis of successive hike in wages over the years showed that Tripura and Gujarat experienced negative growth rate and very small positive growth rate is experienced by Meghalaya and Jammu and Kashmir. Highest growth rate is experienced by Himachal Pradesh, Odisha, Rajasthan and Bihar. A general trend observed in the growth rate is that states with high wage rate shows slow or negative growth rate for example Jammu and Kashmir and Kerala whereas the states with low wage rate shows high growth rate like Odisha, Bihar and Uttar Pradesh. Coefficient of correlation between compound annual growth rate of agricultural labor real wages and average agricultural real wages of states is negative which again indicates that states having high real wages showed lesser growth whereas as states having low wages rates experienced higher growth rate. This is because development of connectivity, transport and communication technology allowing free and unrestricted movement of labors loaded with required information and knowledge. This eventually is leading towards creating an equilibrium of wages across the country by filling the demand and supply gap.

Conclusion

Agricultural labors are among the most deprived section (economically, socially, politically) of rural society having meagre resources to sustain a meaningful, dignified life. Major and sometimes the only source of their income is the wages they derive by working in fields of others and other related allied activities. Decline in their wage or relatively slow growth as compared to inflation would have harsh impact on their development. Decline in agricultural laborer's wages would lead to reduction in purchasing power and demand of products and services thus slowdown in production process that would again hit the consumption as reduced production would cause increased unemployment, decline in capacity to spend for education, health, skill development. Agricultural labor wages depend upon demand and supply of labors thus in order to increase their wages their supply need to be cut short by engaging them in other sector of economy like decentralized micro, small, medium manufacturing enterprises, food processing industry, providing them with skill training for making them ready for semi-skilled jobs and increasing their demand by promoting farming practices that are more convention, integrated, labor intensive, and natural farming. Community farming or cooperative supported animal husbandry could support their household income and reduce vulnerability. Efforts are needed at central and state policy making level, by demotivating farm mechanization especially at those states that are labor surplus by introduction of seeds and techniques that engulfs more labor and support farmers financially to incur the increased cost of production thus tackling the problem of unemployment, reducing wages of agricultural labors and excessive rural to urban migration in one go.

INCLUSIVE GROWTH: ROLE OF MIGRATION

Dr. Geeta Devi

Abstract

Migration has an intimate association with the development and inclusive growth. While development causes migration the converse is also true. No doubt migration depri ves the society of origin of its young energetic creative manpower, but the remittances sent by them give rise to not only a number of developmental activities but also creates opportunities for all the section of the society in one way or the other. Remittances are most important to development though this depend on a variety of factors as the propensity to remit differs from person to person. Nevertheless, remittances helped in generating employment through the investments made by the migrant households thus helped the migrants and non-migrants equally. Remittances also helped in improving the standard of living of people through enhancing their consumption levels, thus having a multiplier effect on the economy. As the policymakers have shifted the focus away from the quantity of growth to the quality of growth, this paper is an attempt to highlight the key issues regarding the inclusive growth and how migration can impact inclusive growth. Therefore, the main objective of the present research is to know the role of migration in helping for an inclusive growth. To properly understand the relationship between remittance, migration and inclusive growth we need to look beyond household income effects and consider wider social impacts. In the present study the discussion is based on migration and inflow and use of remittances leading to poverty alleviation, migration and inequality, migration and changes in social institutions, and migration and change in role of women.

Introduction

Increasing migration flows in recent decades have been an important element of economic integration at both the global and regional levels, notably in Asia. The main drivers of migration in Asia, as elsewhere, are the wage gap between origin and destination countries, which remains wide, and the lack of employment

opportunities in origin countries, especially less-educated workers. These factors explain much of intra-regional migration by the low-educated (ADBI, 2013). In recent years, many policymakers have shifted their focus away from a narrow concern with GDP growth towards a broader target of 'inclusive growth.' This concept is understood to encompass both a lasting reduction in absolute poverty and a more equitable distribution of the gains from growth (UN, 2010). Since 2011, the Asian Development Bank Institute (ADBI), together with the Organisation for Economic Co-operation and Development (OECD), have organized an annual Roundtable on Labor Migration in Asia as part of its thematic priority in capacity building to promote regional integration and international cooperation and inclusive growth. The main theme of the second Roundtable, held in January 2012, was Managing Migration to Support Inclusive and Sustainable Growth. (ADBI, 2013). During the Roundtable, participating country-of-origin governments expressed the view that outmigration by educated citizens was largely positive. Governments raising this topic expressed confidence that it provides greater returns to education, and these countries hope to benefit from higher per capita remittance levels, the inclusive growth approach takes a longer term perspective. The emphasis on improving the productive capacity of individuals and creating conducive environment for employment, rather than on income redistribution as a means of increasing incomes for excluded groups. Due to this longer term perspective, there is an explicit focus on structural transformation and internal migration in the inclusive growth analytics framework. In developing countries a significant part of growth is generated through reallocation of labor from low productivity to high-productivity sectors.

Objectives

This paper is an attempt to highlight the key issues regarding the inclusive growth and how migration can impact inclusive growth. Therefore the main objective of the present research work is to know how migration weather internal or international work as a key for an inclusive growth.

Database and Methodology

In order to achieve the objectives of the present study, secondary data/ information have been used. The approach adopted for the research work is a systematic literature review strategy. Secondary data was collected from books, reports, journals, research articles having a direct bearing on the subject.

How Migration can help in Impacting an Inclusive Growth

Migration particularly rural to urban migration is one of the most conspicuous processes of the present day. The process can be comprehended in terms of the cause and consequences of migration in relation to the communities of the origin and destination of the migrants. The community structure generates situations which compel the people to make a move on the one hand and, on the other, the process of migration brings about changes in the community structure itself. Migration is a two way process, as it is a cause of development and as well as a consequence of development. The consequences of migration are numerous. These however are difficult to analyze as it involves a number of units and depends also on various factors at the place of origin and place of destination. The rapid growth of cities in the developing world is the major impact of migration. In the 20th century, rural-urban migration was viewed favorably in the economic development literature (Todaro, 1977). Internal migration was thought to be a natural process in which surplus labor was gradually withdrawn from the rural sector to provide needed manpower for urban industrial growth. The process was deemed socially beneficial since human resources were being shifted to locations where their social marginal products were not only positive but also rapidly growing as a result of capital accumulation and technological process. During the growth process, migration has a role to play in bringing about structural changes in the economy.

The consequences of migration are numerous. These however, are difficult to analyze because of the involvement of a number of units such as individuals, families, communities, regions and countries as well as intermediating variables like the socio-economic, political, environmental and cultural background and prevailing conditions at the place of origin and place of destination. Further, quite often, migration has more indirect than direct effects at the places of origin and destination and that too of variable temporal dimensions (U.N., 1984). Impacts of migration depend on the contexts, such as seasonality of movement, educational level of migrants, the length of time spent away, assets and social structures and institutions allowing women and others to pursue activities previously reserved for men and household heads (de Haan, 2000). Therefore to properly understand the relationship between remittance, migration and inclusive growth we need to look beyond household income effects and consider wider social impacts. Migrants impact both the place of origin and destination. And as the links between migration and growth is quite complex as the different aspects of it interacts,

making the quantitative assessments problematic. Therefore, it can observe from the following discussions that how migration impacts economy and society as well leading to an inclusive growth:

Migration and Poverty Reduction

The relationship between migration and poverty is a complex one. Migration can help to reduce poverty and poverty itself is also a cause of migration. But both are deeply interlinked. Researchers on migration have long grappled with the question of whether migration increases or reduces poverty. A consensus has not been achieved partly because of paucity of information and partly because of the tremendous variation across contexts and ethnic groups. The poverty reduction impact depends on a variety of factors like the availability of surplus labour with in the household and village and whether migration increases labour scarcity. Due to a tightening of domestic labor market (both agriculture and non-agriculture); however, that the wage increased in a higher rate in the agricultural sector shows an increase in employment opportunities and alternative particularly for low-income groups. An increase in wage rates can be a pivotal element for rural growth dynamics (Brown et al, 2013; Housen et al, 2012).

A research in Kenya showed even though poor households have less access to opportunities, income from migration may form a more important part of their income than that of the better-off (Knowles and Anker, 1981). Although most international remittances do not flow directly to the poorest people, remittances often make upon important share of the income of the poor people and poor communities as poor people might be affected indirectly through the economy wide effects of remittances expenditure on wages, prices and employment in migrant sending countries (Taylor et. al.1996). Taking the example of Nepal it has been observed that despite the political upheavals, there is a dramatic fall in poverty level and maintaining a stable level of growth over the past two decades, averaging around 4% annually. This sustained growth and reduction in poverty rate is a contribution of outmigration and remittances and this recent growth is termed as an inclusive growth (Maskay and Adhikari, 2013). Teto (2001) estimated that 1.7 million (out of 30 million) Moroccans would fall back into absolute poverty without international remittances and the proportion living below the poverty line would increase from 19 to 23.2 per cent. Another analysis of Egyptian and Ghanian survey data equally indicates that migration enables poor people to move out of poverty. Afsar (2003) also argues that migration has reduced poverty directly and indirectly in Bangladesh as remittances have expanded the area under cultivation and rural labour markets

by making land available for tenancy. Morina, D., Gashi, P. and Morina K., 2015 had observed in their study on Kosovo, that migration is a selective process that affects the growth potential and the welfare of non-migrants as well.

Anh's (2003) conclusions based on data from China, Vietnam, Phillipines and Bangladesh identifies migration as a driver of growth and important route out of poverty with significant positive impacts on people's livelihood and wellbeing. Research by the World Bank and other institutions points to a positive correlation between migration and poverty reduction. A study of 74 low and middle income developing countries reveal that on average a10 per cent increase in the number of international migration in a country's population can lead to a 1.2 per cent decline in poverty (Page and Adams,2004). Therefore, it seems to be of little doubt that migration can reduce poverty and stimulate economic growth (Deshingkar and Gramm, 2004). Migration may have direct and indirect effects on poverty. It can directly reduce poverty by reducing the number of people that a poor household must support. If the potential migrant was not working before leaving, this effect is particularly beneficial. Migration helps stabilize the household income and prevent the household from plunging further into poverty. Migration and migrant can have indirect effects on poverty in the migrant's home community. Migrants leave the local labour force making local labour force more scarce and pressuring the wages upwards, while remittances adds liquidity to local market, potentially stimulating economic activity (de Brauw, 2007).

Migration and Inequality

A commonly held view is that migration increases inequality. The effects of rural out migration on economic welfare in sending areas depends critically on how emigration effects the local capital-labour ratio among non-migrants, that is, on the distributional effects of migration. Moreover, an important concern of the literature on migration is that the poorest are rarely found the major beneficiaries of remittances, at least directly. This is due to the inability to finance expansive moves such as those overseas or those requiring some degree of education. Thus, the impact of migration and remittances on income distribution and in source regions remains a matter of interest in the literature but also of some dispute. The effects of remittances on income distribution and other aspects of wealth is primarily a function of migration selectivity. If migrants mainly originate from relatively wealthy households, migration is more likely to imply greater inequality in the community of origin, while the reverse seems likely if migrants come from relatively poor households, as in the case of Indian rural to urban migration, it has been emphasized

that better off migrants are "pulled" towards better job prospects while the poor are "pushed". "Push" and "pull" migration are twin children of inequality in the same sort of village; but they are also sources of new inequality (Lipton, 1980). It is more correct to say that the impact of migration on income inequality on migrant sending communities vary for different types of migration and for different periods in a community's migration history (see for instance, Stark et.al, 1988). Through the development of social networks between migrants and people staying behind which diminish the risk and costs of migration (Bauer and Zimmermann, 1988), and the flow back of international (Kornar, 1992) less wealthy households initially tend to gain increasingly easy access to international migration. As a consequence of this diffusion process, the initially negative effect of remittances on income inequality might, therefore, be dampened or even reversed in the long term. One might conclude that migration has contributed to increasing household income inequality within a certain community or region however, when comparing this migrant sending region as a whole with other more wealth and centrally located region in the same country (or between countries), one may find that inequality between the region has actually decreased as a consequence of developmental effects of migration (Taylor et. al, 1996). Inequality clearly influences and is in turn, influenced by migration (Waddington, 2003). The search for a better and more secure livelihood drives many migratory movements, and according to Nyberg-Sorensen et. al. (2003), is most common where survival is at stake. Not only does inequality influences who can migrate where, when and how, but it may also be a primary cause of migration. For example, Salemink (2002) shows how internal migration in Vietnam relates to a lack of land rights is customary law for certain excluded social groups. Gaps and access to water and land resource are also documented as causing migration in South Africa (Rwelamira et.al, 2000), Cameroon (Schrider and Knerr, 2000), West Bengal (Ragaly, 2003) and tribal Western India (Mosse et. al, 2002). Here, however the concern is more with how migration influences inequality. Although inequality increasing effects, have been found in various studies at the regional (Adams, 1989) and national (Mishra, 2007) levels, this mechanism is not inevitable.

Migration and changes in Social Institutions

Several historical and empirical studies of immigration have recognized and confirmed that the concentration of particular nationality and ethnic groups in certain cities facilitated the migration of the same groups to these cities (Levy and Wadycki, 1973). Networks play an important role in migration. Kinship ties, friendship and shared community origins are hypothesized to increase migration flows because

they reduce the psychic and risk costs of immigration. These networks connection constitute a valuable social capital that migrants can drop on to gain access to foreign employment and better wages and working conditions (Boyd, 1989).

Massy (1989) has made a case for networks under the assumptions of a risk-diversification model. According to this model families allocate member labour within the constraint of their own needs and aspirations in a cost-efficient and risk minimizing way. Moreover, modernization and development create social and economic dislocations that intensify the unstable and unpredictable economic environment created by the usual risks of drought, crop failure and natural disasters, for rural as well as urban areas. In the absence of other ways to ensure against such risks, diversifications of family members location minimize overall family income risk (Massey, 1989). Networks promote the independence migratory flows for two reasons. First, once network connections reach some threshold level, they amount to an autonomous social structure that supports immigration. This support arises from the reduced social and economic and emotional costs of immigration that network permit. That is, network supported migrants have important help in arranging transportation, finding housing and jobs in their place of destination and in effecting a satisfactory personal and emotional adjustment to what is often a difficult situation of cultural marginality.

These benefits make migration easier, thus encouraging people to migrate who would otherwise have stayed at home unless migrants are uprooted. Education appears to be a major factor in who benefits from and is able to undertake migration with in a community, even if this is only in relative terms (Skeledon, 1997). As stated by the Tilak (2007) also "education is the most critical ele¬ment in empowering people with skills and knowledge and giv¬ing them access to productive employment in the future". Therefore, education is an important sphere of wellbeing that can be affected by migration and a livelihood outcome in its own right. Through migration, individuals may be educated or skilled (i.e. it may be a motive to migrate itself) assuring migration is an accumulated strategy thus future generation may benefit through investment in their education (Waddington, 2003). Expenditure in areas such as education, health, food, medicines and investment in housing as well as community projects for education, health and recreational facilities can enhance people's wellbeing and ability to lead the lives they have reason to value. De Haan (2000) reviews literature from parts of India. Zimbabwe and Kenya finding on balance. That migrants are more educated as education can assist the development of critical consciousness and expose individuals to different values and norms.

Where women are educated they are able to participate in transnational migration and entrepreneurship, sending remittances that help to sustain social networks and participating in migrant organization (Nyberg-Sorenson, 2002).

Work in different parts of India by Parry (2003), De Neve (2003) and de Haan (2003) documents how networks are important even, crucial assets to enable migration. This may be through kinship or other kinds of social affiliation and identities such as caste solidarity. In the former, dependency patronage and other kinds of support (e.g. business partnership) can lead to upward mobility. For the later, the village community can be a good source of information and help with alternatives. In west Bengal, Rogaly (2003) reports how migrants establish long term relations with individual employers, which are crucial for survival. De Haan (2003) reports that caste identity plays a role in the personal networks that mediate migration of migrants to Calcutta. Migration can reinforce the structures, ideologies and support networks for development works and also influence positively institutions such as family, school, social norms and traditions and religious organizations by bringing in new progressive ideas into the development of social institutions and also migrants invest in strengthening these local institutions (Haque, 2006).

Women Migration and Empowerment

The most striking example of the social changes in Nepal resulting from out migration has been the empowerment of women in the rural areas. As men have moved abroad to work, women left behind in Nepal have gained increasing autonomy and discretion over household budgets. In a nationally representative survey of married women, more than half of currently married women who earn cash said that they themselves mainly decide on how their cash earnings are used; two in five indicated that the decision is made jointly with their husbands and only 5% said that the decision is made mainly by their husbands. Similarly, the proportion of surveyed married women who earned cash for their work and who solely decided on the use of their cash earnings has increased from 31% in 2006 to 53% in 2011. It is now recognized that gender equality and female empowerment are central to improvements in standards of living and wellbeing (World Development Report, 2011). Further, the empowerment of women in the rural economy has led to drastic changes such as increasing access to information, offering new choices, and providing demonstration effects. Thus, an unforeseen consequence of foreign labor employment to Nepalese labor is that it has spurred societal changes, namely the empowerment of women in rural areas. It has been argued that female migrants show a deeper commitment than male migrants to providing more economic support to

households that are left behind (Osaki, 1999; Carling, 2005; Boyd, 1989). Several studies indicate that until recently migration was dominated by single men (De Haan, 2000), but things are now changing and feminization of migration is now occurring. In India, regional differences in women's mobility have been noted by Singh (1984 cited in De haan,2000), where migration among women in South India is higher than their northern sisters who live in a cultural milieu that is similar to West Asian and North African Arab countries. Bremen (1996) observed that migrant women in Gujarat, India carrying out equivalent tasks to migrant men earned lower wages. It is sometimes assumed that the migration of men encourages the emancipation of women who stay behind since behind since in their husband's absence, women's responsibilities, autonomy and power would increase (see, for instance, Fadloullah et. al, 2001), while remittances enable these women to assert this newly acquired independence. The pattern in China is still largely male-dominated as a number of studies have established (Zhao, 2001, 2003) both due to cultural reasons restricting female mobility and the nature of the demand for manual workers in urban areas. But more women are migrating to labour intensive industries in areas such as Guangdong. Regional comparisons show that women's migration is very high in South America and South East Asia (Guest, 2003). For example, a study of the cities of Ho Noi and Ho Chi Minh estimates that 40-45 per cent migrants are female (Grace, 2002).

There is micro evidence from several countries in South East Asia that the levels of female migration have increased over recent decades. The employment of women is greatest in the five major export-oriented, labour intensive industries, which are electrical machinary, electronics and computer parts; textiles and readymade garments; frozen and canned foods; precious stones and jewellery and footwears (Clawn,2002). The majority of female rural-urban migrants in East and South East Asia are young and unmarried and the concentration of this group in urban areas is partially in the mega cities (Guest, 2003). This form of migration has increased and become more socially acceptable in South Asia (Siddiqui, 2003). In some areas cultural barriers are breaking down because of the huge opportunities offered by migratory work. Migration thus offers many prospects for helping women to exit from poverty (Deshingkar and Grimm, 2004). It is now recognized that, international migration is positively associated with the status of a women and the opportunities for women to go abroad for employment draws from changes of role of women in areas such as household's decision making, division of labour, gender roles and community perception. Gammage (2004) found that, through migration

and remittances, Haitian women have been able to change the political landscape of Haiti and have challenged traditional gender roles. The so called, "autonomous female migration", has increased because of a greater demand for female labour in certain services and industries and not just as accompanying spouses.

The feminization of migration is one of the principal recent changes of population movement. Today women account for about half of the migrant population (Haque, 2006). Both Courbage (1996) and Fargues (2006) hypothesized that besides factors such as older age of marriage, increased female labour participation and improved education migration from North America to European countries has contributed to the diffusion and adoption of European marriage patterns and small family norms and so has played an accelerating role in the demographic transition. Blue (2004) found that females were positively associated with remittances behaviour among Cuban emigrants. The changes in the family and social norms brought by the female migrants are insignificant and potentially beneficial for the society (Haque, 2006).

Conclusion

Inclusive growth is regarded as the new mantra of development. This paper looks at the approach to the building up of a relationship between inclusive growth and migration and how migration is impacting it. Though many have argued that migration deprives poor countries of its valuable human resources, but studies also have proved that migrants are a potential source of development to their origin as they bring with them the new skills, advanced technology and also potential sources of finance in the form of remittances sent by them. Therefore, it can be concluded that migration does not always lead to brain drain but also to brain gain. Therefore, migration weather internal or international promotes the welfare of the economies and help in bringing an inclusive growth and development directly or indirectly, through the helps provided by the migrants to the area of destination or origin, such as construction of houses and cattle sheds, purchase of land and livestock economy, introduction of new farm technology, education etc. To continue the process of economic growth and social transformation to which remittances are contributing, the economies should foster an economic environment conducive to the productive use of remittances. Therefore, migration weather internal or international promotes the welfare of the economies and help in bringing an inclusive growth and developmental process directly or indirectly. To continue the process of economic growth and social transformation to which remittances are contributing, the economies should foster an economic environment conducive to the productive use of remittances. In particular it should maintain a reasonable level

of economic stability through building consensus among the political parties on minimum common economic agenda for development and growth.

Abstract

The paper discussed the status, prospects, and challenges of sustainable tourism in Andaman and Nicobar Islands. It has been found that there is huge potentiality of sustainable tourism in the islands. Unexplored geographical features, diversified biodiversity, rich cultural heritage, rich tribal culture, evergreen forests, wild life sanctuaries, and river tributes, are prominent factors for the potential growth of the tourism sector. Travellers can enjoy the village life of the local tribes. The islands have plenty of marine wildlife, and amphibian. Cellular Jail National Memorial, Chatham Saw Mil, Samudrika Naval Museum, Anthropological Museum, Corbyn's Cove, Sound and Light Show are the popular places. But, there are also challenges before the tourism industry. Therefore, government should implement policies for mitigating such challenges.

Introduction

The term tourism was introduced in the 19th century and it is associated with the term "sustainable tourism". Tourism industry is important for any country, because it surge growth and demand of products/services of industries in the country. Tourism has the cultural, and economic phenomenon, where people move from one place to another for multiple purposes. It is the short period or temporally movement from the native place. Duration of the visit may be just one night, or up to one year. It always includes the domestic tourism, inbound tourism, and outbound tourism. Tourism industry is considered as a bigger industry in terms of employment and foreign earnings. It improving the communications among the peoples and solving various social disputes. It has many benefits, such as introduction of new technologies, boost in economic activities, infrastructure development, increase global connectivity, source of foreign exchange earnings, improve nations brand image, improvement of living standards, cultural growth etc. Sustainable tourism involved in development of both the present and future generation. It means movement of people outside own houses and visit various

places without harming the natural environment. Sustainable ecotourism benefits both the visitors and the local peoples. It is useful for swelling conservation and economic growth. Travellers can witness the beauty of the natural environment and also learn about the culture of the ethnic peoples. Ecotourism is natural based activities that increases the interest of people about certain places. Such activities will be economically, ecologically, and socially sustainable and helpful for the wellbeing and conservation of the areas. Local people will be benefited through such tourism without affecting their culture and customs.

Objectives

The main objective of this study is to investigate the prospects of sustainable tourism in Andaman and Nicobar Islands, and to study the challenges before the tourism sector.

Study Region

Andaman and Nicobar Islands is a union territory of India. It contains two island groups, Nicobar Islands, and Andaman Islands. The total land area of the islands is nearly 8,249 km^2. There are 572 islands. Port Blair is the capital of the union territory. It is situated 1,255 km from Kolkata, 1,200 km from Visakhapatnam, and 1,190 km from Chennai. Hindi, and English are the official languages of the islands. (**Fig.** 1)

Database and Methodology

(1) Design and approach: The present study is based on the secondary data. The data has been collected from reports of Andaman and Nicobar Tourism, and India Tourism Statistics. Various journals and books have also been referred in the present study.

(2) Method of analysis: To reveal the growth of tourism industry of Andaman and Nicobar Islands in general and the sustainable perspectives of the industry in particular, different methods of qualitative analysis comprising of tabulation and text analysis were performed.

(3) Hypothesis: Data analyses have been done on the following hypotheses:

H0: There are no impact of corona pandemic on the Tourism Industry in Andaman and Nicobar Islands.

H1: There are impact of corona pandemic on the Tourism Industry in Andaman and Nicobar Islands.

Results and Discussion

Tourism industry in Andaman and Nicobar Islands are increasing due to the beautiful beaches, and adventure sports like sea-walking, and snorkelling. Its tropical rain forest is rich with a diversity of animal life. Kalpong River, Alexandra River, Galathea River, and Dagmar River are the popular rivers. Kalpong river situated in Andaman District, are originated from Saddle Peak. The remaining three rivers situated in Great Nicobar. Hydroelectric dam is constructed on the Kalpong River. The top tourist visited places are Port Blair, Havelock Island, Neil Island, Ross Island, Diglipur, Long Island, Cinque Island, Mayabunder, and Little Andaman. Port Blair is the capital and headquarter of Andaman and Nicobar Islands. It is the gateway for the others incredible islands. Veer Savarkar International Airport is the only airport in the islands. It is well connected with the mainland by air from Visakhapatnam, Chennai, and Kolkata. Cellular Jail National Memorial, Chatham Saw Mil, Samudrika Naval Museum, Anthropological Museum, Corbyn's Cove, Sound and Light Show are the popular places of the city. Cellular Jail is a British colonial prison. Today it is a national memorial monument. Wandoor Beach is situated 25 km south-west of Port Blair. It is located near the Mahatma Gandhi Marine National Park. There are plenty of marine wildlife, and amphibian. Saltwater crocodiles are often found on the coasts. Wandoor is also recognized for its Mangroov forest, lagoons, and backwater. Travellers can enjoy the village life of the local people. Agriculture crops (coconut, and paddy) and fishing are the main sources of income of villagers. Travellers can see the rural life of the diversified tribes. It will enhance the rural tourism in the islands.

Table-1 discussed the populations and areas in Andaman and Nicobar Islands. It has been found that south Andaman district have the largest number of population, followed by the North. and Middle Andaman districts. It is the largest district followed by the South Andaman district. Mahatma Gandhi Marine National Park was established in 24th May 1983 under the Wildlife Protection Act of 1972 for the protection of nesting sea turtles, and corals. Twin Islands and Labyrinth Islands are the two major island groups in the park. Majority of the coral reefs are fringing reefs. There are nearly some 20 islands and rocks in the park. Many islands are covered with thick mangrove vegetation, sheet rocks, uprooted trees, and sand covered beaches. There is scope of ecotourism in Red Skin and Jolly Buoy islands. Havelock island is a popular eco-tourism spot. Water sports like as scuba diving, banana boat ride, and sea walking are popular among the tourist.

Elephant beach, Kala Patthar beach, and Radhanagar beach are the popular beaches. Tourist can also enjoy the mangrove safari, fishing, trekking, scuba diving etc. Neil Island is situated 40 Km. away from Port Blair. Sitapur beach, Laxmanpur beach, and Bharatpur beach are popular beaches of Neil Island. Travellers can witnessing the unexplored coral reefs. Ross Island is an uninhabited island. The ruins and a small museum of Indian Navy is the main attraction of the island. Ross Island is located three km. east from central Port Blair. There are many lighthouse towers. Peacocks and spotted deer are easily available in the island. Palm and coconut trees are the native trees of the island. Travellers can see the amazing landscapes and sunset views in the evening. (**Table-**1 and 2)

Table-1: The Populations and Areas in Andaman and Nicobar Islands

District	Capital	Population (2001)	Population (2011)	Area (km.)
South Andaman	Port Blair	208,471	238,142	2,640
N. and M. Andaman	Mayabunder	105,613	105,597	3,536
Nicobar	Car Nicobar	42,068	36,842	1,765
Totals		356,152	380,581	7,950

Table-2 discussed the historical population growth in Andaman and Nicobar Islands. It has been found that except 1041-1951 period, in other periods population was increased. Viper Island lies four kilometres west of Port Blair. It is popular among the tourist because for its mesmeric picnic spots, and having historical

importance. Nali, Mud Spitting Volcano, and Kalipur beach are the popular places of the island. Saddle Peak National Park, Orange gardens, paddy fields, Saddle Peak, and expansive greenery and marine life are other tourist attractions. Trekking, scuba diving, and snorkeling are the common activities. Long island has the beautiful eco-huts headed by Blue Planet. Merk Bay, and Lalaji Bay are the popular sports. Clinque Island is a human inhabited island. Tourist can enjoy the wildlife, greenery, and marine life of the island. The Mahatma Gandhi Marine National Park, salt water crocodile, starfish, sea weeds, varieties of coral reefs, fishes, shells, turtles, and sprawling marine life are the major tourist attractions. Mayabunder situated in middle Andamans. It is cultural hub of 71 villages where majority of people are immigrated from Pakistan and Bangladesh. Karmatang beach, and Karmatang Beach have the turtle nesting spots. Little Andaman is paradise for the natural lovers. Travellers can involve in coral watching, fishing, diving, snorkeling, surfing etc. Beautiful beaches, Red Oil Palm Plantation, evergreen rain forests, and waterfalls adds additional satisfactions to the tourist. (**Table-**3)

Table-3: Year-wise Arrivals of Tourist in Andaman and Nicobar Islands.

Years	Tourist Visits			Percentage Share		Rank

Source: India Tourism Statistics.

The above **Table-**3 discussed the arrivals of tourist in Andaman and Nicobar Islands. It has been found that number of tourist are increasing continuously since 2010, but declined in 2020, due to the corona pandemic. Domestic tourist arrival was more than 50 thousand in 2019, but it was dropped to only 126238 in 2021. On the other hand, foreign tourist arrivals were 16206 in 2019, and it was just 1687 in 2021. Lockdowns, and travelling restriction due to the corona pandemic is main factors behind the sudden drop of the tourist arrivals. Therefore, the null hypothesis is rejected and alternative hypothesis is accepted, i.e. there is impact of corona pandemic on the Tourism Industry in Andaman and Nicobar Islands. There are three districts in Andaman and Nicobar Islands. They are Nicobar, South Andaman, and North and Middle Andaman. Malacca is the capital of Nicobar district. It is situated in Car Nicobar tehsil. Car Nicobar is located in the northernmost of Nicobar Islands. It is popular for the silvery beach. It is flat island with clusters of coconut palms, and areca nut. It is a small island (only 126.9 km^2). There are 21 villages. It has tropical monsoon climate. Bird watching is popular among the tourist. Green imperial pigeons, Andaman boobooks, White-headed starlings, Andaman cuckoo-doves, Andaman wood pigeons, and Nicobar serpent-eagles are the prominent birds. Car Nicobar is 260 kilometers, far away from Port Blair.

Ship service is available between the two towns, and travellers can collect ticket from the office of the Director, Shipping services, Port Blair. Indian Air Force operating the charter services between Car Nicobar Air Force Base, and Port Blair's Veer Savarkar International Airport, Campbell Bay. Regular service of Pawan Hans helicopter is also available. Mount Thullier is the highest point of Nicobar Island. It is 642 meter above the sea level. Dak Tayal, Dak Aniang, Amrit Kaur, Jubilee, and Galathea are the popular rivers of the island originated from Mount Thullier. Among the rivers, Galathea River is the longest river. Indian passport holders can travel the island, but the foreign passport holder's needs Landing Permits from the Office of the Deputy Commissioner, Andaman District. Indira Point is the most southern point of Great Nicobar Island. Great Nicobar Island is declared as World Network of Biosphere Reserves by the UNESCO. The island is comprising three distinct groups- Northern Group, Central Group, and Southern Group. Nicobarese, Shompen, and Mainland Indians are the ethnic tribes. Galathea National Park, and Campbell Bay National Park of Great Nicobar are protected areas. The island has the tropical climate. Mayabunder is the headquarter of North -Middle Andaman district. It is connected with Port Blair by the Andaman Trunk Road. It is the major highway. This highway connected Diglipur and Port Blair, via Mayabunder,

Nimbudera, Billy Ground, Rangat, Kadamtala, Baratang, and Ferrargunj. The distance between the two places are 242 km. Ferry service also available between them. It is a waystation for several tourist attractions, like as Karamatang Beach (13 km), beach at Aves Island (30 minutes by boat), and mangrove lined tidal creeks. Majority of the population of union territory lives in this district. Port Blair is the headquarter of South Andaman district. It is also the capital of Union territory. It is connected with the main land of the country by sea, and air. Other towns are Garacharma, Prothrapur, and Bambooflat. Bambooflat is located nearly 13 Kilometers from Port Blair. (**Table-**4)

Table-4: District-wise Popular Tourist Places in Andaman and Nicobar Islands.

District	Popular Tourist Places
South Andaman	Jolly Bouy, Swaraj Dweep (Radha Nagar Beach), Netaji Subhash Chandra Bose Island, Chatham Island, Cinque Island, Corbyn's Cove Beach, Cellular Jail, Mount Harriet, Gandhi Park, and Shaheed Dweep.
North- Middle Andaman	Lamiya Bay Beach, Karmatang Beach, Ramnagar Beach, Mud Volcano at Shyam nagar, Kalpong Hydro Electricity, Limestone Caves in Diglipur, Twin Islands - Ross & Smith Islands, Saddle Peak, Kalipur Beach and Turtle Nesting Ground.
Nicobar	Little Nicobar, Great Nicobar, and Car Nicobar.

Source: Official website of the districts.

Table-4 exhibits the popular tourist places in districts of Andaman and Nicobar Islands. It has been found that tourist places are scattered in the districts. Lamiya bay beach is situated in the foothill of Saddle Peak. It is near the Kalipur beach. Karmatang beach is perfect place for the snorkelling and scuba diving. Travellers can observe the olive ridley turtles, hawksbill turtles, green ocean turtles, and leatherback turtle. Ramnagar beach located 35 kilometers from Diglipu. It is more suitable for suitable for swimming. turtle nest is easily available. The beach has the eco-friendly beach facilities, like as seating arrangements, and eco-huts. Mud Volcano located near Hathilevel. The chain of Mud volcanoes can observe in the green jungle of Shyamnagar. Seating facilities along with information boards are available for the tourists. Kalpong dam is constructed on the across Kalpong river at Nabagram. It is only dam in the Union Territory. Turtle Nesting takes place at

Ramanagar beach and Kalipur beach are popular among the tourist. It is the home to thousands of turtles during their nesting period. Alfred caves is located near the Ramnagar beach. Ross & Smith islands are popular among the tourists. There is a marine sanctuary. It is enclosed by tropical forests. It is the perfect place of trekking and trail hiking. Diglipur is popular for eco-friendly tourists. It is a beautiful place having the orange garden paddy field, forest, and marine life. Andaman and Nicobar Islands are enriched in culture & heritage. Folklore is narrated and folk songs are the part of the festivals. There are many indigenous peoples in the islands. Andamanese are a listed as scheduled tribe as per India's constitution. Traditionally they lived a hunter-gatherer lifestyle, Great Andamanese and Jarawas are the major tribes. Jarawasve lives in Middle and South Andaman Islands. According 2011 Indian census, their population is 380. They are hesitated interaction with outsiders. Tourism department of the Andaman and Nicobar administration issued warning for attempting photographing them, or contact with Jarawas. They are protected under the under the Protection of Aboriginal Tribes Regulation, 1956. Onge is the another tribe. They live in Little Andaman. Their belief system is a form of animism. They are still maintaining their cultural and biological identity. Their population is declining due to their food habits brought about by their contact with the outside world. Therefore, there are huge potentiality of sustainable tourism in the islands. Unexplored geographical features, diversified biodiversity, rich cultural heritage, rich tribal culture, evergreen forests, wild life sanctuaries, and river tributes, are prominent factor for the potential growth of the tourism sector. But, there are also challenges before the tourism industry. Lack of media coverage, ethnic conflicts, lack of alternatives means of transport, boundary issues, poor connectivity, and abysmal infrastructure are the major challenges before the sector.

Conclusion

There is enormous potentiality of sustainable tourism in Andaman and Nicobar Islands. Port Blair is the capital, and the largest city. It is well connected with mainland by air and sea. Cellular Jail National Memorial, Chatham Saw Mil, Anthropological Museum, Corbyn's Cove, Sound and Light Show are the popular places of the city. The top tourist visited places in the islands are Port Blair, Havelock Island, Neil Island, Ross Island, Diglipur, Long Island, Cinque island, Mayabunder, and Little Andaman. Havelock island is a popular eco-tourism spot. Water sports like as scuba diving, banana boat ride, and sea walking are popular among the tourist. Elephant beach, Kala Patthar beach, and Radhanagar beach are the popular beaches. Diglipur is popular among the tourist because for its mesmeric picnic

spots, and historical importance. It is a beautiful place having the orange garden paddy field, forest, and marine life. Travellers can observe the olive ridley turtles, hawksbill turtles, green ocean turtles, and leatherback turtle. Great Nicobar Island is declared as World Network of Biosphere Reserves by the UNESCO. Andaman and Nicobar Islands are enriched in culture & heritage. There are many indigenous peoples in the islands. So, there are huge potentiality of sustainable tourism in the Union-Territory. But certain factors, like as ethnic conflicts, poor connectivity, lack of media coverage, lack of alternatives means of transport, boundary issues, and abysmal infrastructure are the major challenges before the sector.

HISTOGENESIS AND GROWTH OF PATNA METROPOLITAN CITY

Dr. Anjani Kumar and Professor Ram Sakal Yadava

Abstract

"Every place is a history of a life" (Tuan, 1977). Studying the histogenesis and growth of a historical city is not merely an exercise in understanding the past but it is an exploration of the transformative power of human civilization in crafting the urban environment as well. Examination of historical evolution of a city "illuminates the hidden relationships between power and space, revealing a deeply rooted interplay of social and spatial transformations" (Soja, 2010). This research paper delves into the histogenesis and growth of Patna settlement, a city of profound historical significance in India. Through an in-depth examination of historical records, maps and demographic data, this study traces the city's growth, from its ancient origin as Patliputra to its current status as a bustling metropolitan area. The research scrutinizes spatial expansion, population dynamics and key socio-political events that have shaped Patna's trajectory over millennia. The study reveals the pivotal role of strategic location along the Ganga river (Prasad, 2008), successive dynasties (Thapar, 2013) and colonial influence (Rai, 2010) in shaping the Patna's urban landscape. The analysis further delves into post-independence challenges, including economic decline and administrative restructuring, particularly following the separation of Jharkhand from Bihar in 2000. Despite these challenges, Patna's resilience is evident in its population growth which has multiplied tenfold since the early 20th century. This study projects a population of over 4 million by 2051, underlining the city's continued vitality and potential for further expansion. This comprehensive historical account contributes to a better understanding of the city's urban development processes and provides a foundation for urban planning and development in the future.

Introduction

To ensure a better future, it is vital to learn from the past. In order to comprehend the processes and patterns of urban development, it is essential to study the origin, evolution, and growth of cities. An examination of the histogenesis of a city is

necessary to properly comprehend the process of urbanization. The origin of ancient cities is often linked to myths, legends and divine interventions. The discipline of urban geography is concerned with the precise study of a city's location, site and situation in a temporal context. Recent advancements in underground exploration surveying technology have provided a gateway to search for 'city seeds' (Bosker, 2022). The development of cities is intricately tied to the progress of humanity and civilization. While traces of human civilization have been found worldwide, the civilization of the Indian sub-continent has an antecedence of urban nature. The Harappan civilization provides evidence of urban infrastructure such as proper drains, planned housing, lanes, and roads. Furthermore, several cities in mainland India are assumed to have divine origins dating back thousands of years, including Varanasi, Mathura, and Dwarika. Patna city has a history dating back to the 6th century BCE or even earlier. Apart from the Kumhrar excavation, there is no significant evidence of infrastructural traces to date. Historical and religious texts have always made appropriate mentions of Patna's expansion up to the pre-historical Mahabharat period. The travel accounts of foreigners during the ancient period also mention Patna under different names such as Pataliputra, Palibotra (Greek), and so on. The city has been given many names during the rule of different dynasties in the ancient history of the Indian sub-continent. As with other ancient cities, Patna's origin has evinced conflicting claims.

Study Region

Patna, the capital of Bihar, holds a prominent place in the historical and geographical landscape of India. This city, located in the west-central region of the Bihar state, lies in the midst of the fertile Ganga plain. The city falls within the coordinates of latitude 25°30' to 25°40' North and longitude 85°0' to 85°15' East. The city is surrounded on three sides by the Ganga, Sone, and Punpun rivers, and it boasts a unique convergence of four rivers with the Gandak river to the north. The Ganga's southern embankment forms the city's northern boundary, while the Punpun river flows approximately 5 kilometres to the south and the Son river more than 10 kilometres to the west. The city's elevation, averaging 55 meters above mean sea level, encounters lower areas to the southeast that are susceptible to prolonged waterlogging after floods. Most of the metropolitan area is part of the older floodplain, with the western region along the Ganga's embankment classified as an active floodplain. The city's population grew substantially between 1991 and 2011 with a significant "floating" population commuting daily. As of the 2011 census, Patna is home to a population of 2,046,652. The city extends for

about 24 kilometres from east to west, with an average width of 2.5 kilometres and encompasses an area of approximately 142 square kilometres.

Objective

The main objective of this study is to reveal the origin and evolution of the city including its evaluation of its spatial and demographic growth.

Database and Methodology

The study is solely based on secondary sources of data as it delves in to histogenesis and growth of the city. Accessible literature, historical maps, Survey of India Topo-sheets, Census data and other related government reports have been used as secondary data. ArcMap 10.8 has been used to prepare different relevant thematic maps such as extent of urban growth and settlement of urban landscape. MS Excel has been used for data analysis, presentation and interpretation.

Origin

The ancient origins of Patna are steeped in legend, with a multitude of stories surrounding the city's name and foundation. Over the course of its long and illustrious history, Patna has gone by a variety of monikers, from Patligram - a small village named after the patli flower that still grows in the city to this day - to pushpapuri and kusumpura, both of which mean 'city of flowers' and evoke an image of a tranquil city surrounded by blooming gardens. Patliputra is perhaps mostly well-known of these names, a testament to the city's rich cultural and historical heritage as the site of the ancient kingdom of Magadha and the Mauryan empire's flourishing capital. By the time of Sher Shah Suri in the 16th century, Patliputra had evolved into Patna, a name that phonetically resembled the Sanskrit word for 'port', paatan. However, the city underwent another name change when it became known as Azimabad during the Mughal era, named after the Mughal prince Azim-uh-shan, who established a court here. With the fall of the Mughal empire, the people of the city returned to calling it Patna, a name that has endured to this day and is synonymous with images of grand empires, scientific advancement and a rich cultural legacy that remains an integral part of India's history.

Tales and Anecdotes

The narrative from an ancient Hindi manuscript, translated from the Sanskrit Brihatkatha, provides a captivating account of the foundation of Patna. It chronicles the journey of a Brahmin Bhumideva and his sons, Kusa and Bikusa,

along with their wives Pramati and Sumati, who sought their fortune overseas. The intervention of deities Mahadeva and Parvati, prophesizing the birth of a child named Putra with a unique ability to generate a thousand gold coins. Putra, in a gesture of love and identity, established and named Pataliputra after his wife and himself. Following his reign, son Kusuma ascended to the throne, and under his rule, the city was renamed Kusumapur. This narrative intertwines folklore, divine intervention, and urban genesis, offering a rich tapestry of Patna's origin.

Evolution

The city of Patna owes much of its prominence to its strategic location, situated as it is amidst the rivers Ganga, Son, Gandhak, and Punpun. This unique position didn't only ensure its political pre-eminence but also allowed the city to thrive as a hub for riverine trade. Over the centuries, Patna has served as the capital of various powerful dynasties, from the Shishunaga and Nanda to the Maurya, Shunga, Kushana, and Gupta. Each of these dynasties has contributed to the city's cultural and historical heritage, leaving an indelible imprint on its identity. The city has also attracted travellers who found Patna inspiring and wrote vividly about its vibrant personality and historical journey. Patna played a critical role in India's struggle for independence, further cementing its place in the annals of Indian history.

Ancient Period (5th Century BCE to 12th Century CE)

In the 5th century BCE, Ajatashatru of the Haryanka dynasty of Magadh, son of Bimbisara, emerged as a significant ruling figure in Indian history. He was a contemporary of the great souls namely Mahavir and Gautam Buddha. Despite a tumultuous ascent to power, in which he forcefully overtook the kingdom from his father and imprisoned him, Ajatashatru emerged as a successful conqueror. By capturing Vaishali, fortifying a village to form the city of Patliputra, and capturing Kashi and other smaller kingdoms, Ajatashatru secured his position as the ruler of the most powerful kingdom in North India. Between 491 and 961 BCE, Ajatashatru moved the capital of Magadha kingdom from Rajgriha to Patliputra, and his son Udayabhadra succeeded him, leading to the city's growth into the largest city in the region. Although Gautam Buddha visited Patliputra during the last years of his life and prophesied a successful future, he also predicted the city's ruin from Flood, Fire and Feud. In the 4th century BCE, Chandragupta captured Patliputra and established the Mauryan dynasty, which lasted from 321 to 185 BCE. With the rise of the Mauryan dynasty, Patliputra became the centre of power. The city was constructed using wooden structures during this time, with multi-story buildings

and palaces surrounded by ponds and parks. The drainage system was another notable feature of Patliputra. The streets' water route drained into a moat , which functioned as both a defence system and drainage system. In 303 BCE, Greek ambassador Megasthenes visited the royal court of Chandragupta and described Patliputra as an important and fortified city with wooden walls, crowned with 517 towers and 64 gates, all surrounded by a protective ditch. The main gate of the city was protected by a special armed contingent under the kiledar . Megasthenes noted that visitors had to show their identity to the gatekeeper while entering the city. He described Patliputra as a splendid city and compared it to the contemporary Persian sites (Waddell, 1903). In the 3rd century BCE, King Ashoka, the grandson of Chandragupta, extended the Mauryan empire as far as Madras and renovated the wooden capital into a stone construction in 273 BCE. During this time, education and learning received immense state support, leading to Patliputra becoming home to several eminent world-class scholars, including Aryabhata, Ashvaghosha, Chanakya or Kautilya and Vatsyayana. Patliputra was considered the largest city during 300-195 BCE.

Emperor Ashoka's reign marked a significant period of cultural, social, and religious transformation, with his emphasis on Buddhism and his rock and pillar edicts promoting social justice, religious harmony, and non-violence. In 232 BCE, the Mauryan dynasty came to an end with the death of king Ashoka, and the Shungas took control over the kingdom. India then reverted to a group of unfederated kingdoms with the Shungas controlling most of the core territories of Magadha. In the 2nd century BCE, Magadh entered a period of political decline. Although most of the powerful kingdoms were located in the south and west, the north remained culturally active, with Buddhism spreading throughout the region. During the 4th century CE, Patliputra regained prominence under the Gupta dynasty, especially during the reign of Chandragupta I (320-335). He revitalized Magadh by conquering the territory, setting up Patna as the capital and consolidating a kingdom in the eastern region of northern India. Chandragupta I revived some of the principles of king Ashoka's government. However, it was his grandson, Chandragupta II (376-415), who established a vast empire in the north and western Deccan. In the 5th century CE during the reign of Chandragupta II, the Chinese pilgrim Fa Hein visited Patliputra (Po-lien-fu) and recorded the flourishing state of Magadh, as well as the impressive architecture of the city, describing the walls, gates, palaces, and buildings as being constructed in a manner that could not have been accomplished by human hands (**Fig.** 1 and **Fig.** 2). The wooden outer wall that Megasthenes

previously mentioned was still standing in the early 5th century. Patliputra was also home to many stone buildings and a great palace erected by Chandragupta's grandson, Ashok, who had converted to Buddhism. Hiuen Tsang, who travelled through the silk route, visited Patliputra in 1637 CE and found it to be a deserted and crumbling land, as fire, flood, and internal dissension had all left their mark on the city, as predicted by the Buddha. Following the collapse of the Gupta Empire and continuous annexation by the Hunas, Patna experienced a period of uncertainty similar to the rest of India. The territory eventually came under the growing empire of Harshvardhana Samrat, who defeated the Hunsa and took control of the northwest region of India. However, during the 7th century CE, another Chinese pilgrim named Hiuen Tsang visited India and found Patliputra in ruins.

Medieval Period (13th Century to 17th Century)

In the 13th century, with the Turkish conquest of India and the establishment of the Delhi Sultanate, urbanization and cultural development began in Patna. The first Muslim invasion of Bihar occurred in the late 1190s under the rule of Bakhtiyar Khilji, which led to the expansion of Turkish rule in Bihar. From 1206 to 1526, Patna remained a secondary settlement that was subordinate to the town of Bihar. During the Mughal period, provincial administration reached its zenith. Patna re-emerged as a major centre of trade, but not as a capital city. One of its most remarkable periods was under the rule of Sher Shah Suri, who hailed from Sasaram and revived Patna in the mid-16th century. On his return from Bengal in 1541, Sher Shah arrived in Patna, and while standing on the bank of the river Ganga, he had a revelation that if a fort were built in that location, the water of the Ganges could not flow too far away from it, and Patna would become one of the great towns of the country. Sher Shah's words were put into action when he founded a fort in Patna, which enabled Patna to regain its identity as a hub of power and trade. However, the fort did not last, but the mosque built by him in 1545 survived, and it was built in Afghan architectural elegance with numerous tombs inside.

The earliest mosque in Patna dates back to 1489, built by one of the rulers of Bengal, Alauddin Hussani Shah. The locals call it Begu Hajjam's mosque in honour of a barber who repaired it in 1646. In 1574, the great Mughal emperor Akbar came to Patna to defeat Daud Khan, an Afghan chief. Akbar's secretary described Patna as a flourishing centre for paper, stone, and glass industries. He also mentioned the good quality of various strains of rice grown in Patna. In 1704, Patna was renamed Azimabad, after the grandson of Mughal emperor Aurangzeb, Azim, at the time when he was subedar of Patna (Boyk 2015). Other than the name, very little change

took place during that period. After the decline of the Mughal period, Patna was in the hands of the Nawabs of Bengal. At that time, the city was taken over by Jagirdars who claimed themselves as Nawabs. The Nawabs of Bengal imposed heavy taxes on people but allowed them to flourish commercially. During the 17th century, Patna became the hub of international trade. Much of the lost glory of Patna was revived during the medieval period, giving it a new identity as a medieval city in terms of function and structure under the Afghans and Mughals. The city almost emerged in the same area where it existed in ancient times.

British Period

Patna attracted the next generation of travellers, including Englishman Thomas Roe, who visited in the 17th century and spoke of the four rivers surrounding Patna, each of which served as a valuable waterway for trade. Ralph Fitch, a merchant, reached Patna in the 16th century via one of these riverine routes and observed a flourishing cotton and sugar trade, as well as the infamous opium business. Jean Baptiste Tavernier, a French traveller, visited in 1620 and described Patna as the largest town in Bengal and the most famous for trade, particularly for the exquisitely crafted coral and amber bracelets available in the city's market. By the 17th century, Patna had become a favourite port town for the Dutch, the British East India Company, and merchants from Central Asia, Armenia, and Portugal. In the 1620s, the British established a factory in Patna for the purpose of buying and storing cotton and silk, which soon became a bustling market for saltpetre (Hashmi, 2018). The French, Danes, Dutch, and Portuguese were all drawn to this attractive business, leading to the establishment of several European factories and godowns in Patna, which earned the reputation of being a lucrative location for merchants. In 1632, Peter Mundy declared Patna as the greatest mart in the eastern region. On October 6th, 1763, Nawab Mir Qasim was imprisoned and that led to killings of 45 members of the East India Company (Martin, 1838). Although they had been trading in Patna since 1620, when they established a factory for saltpetre, the British gained control of the city in 1765. After the Battle of Buxar, which took place 115 km west of Patna, the British East India Company was established in East India. Patna soon developed into a strategic centre for trade and regained its lost glory under British rule. Following the Delhi Darbar of 1911, the province of Awadh was divided, creating a separate province of Bihar, with Patna selected as its centre of power and capital city. No matter when, why, or for how long one visited, it was impossible to leave this city without a souvenir, be it a precious commodity from its market or an experience worth immortalizing in writing. After the partition of Bengal presidency

in 1912 (Ahmad, 1988), the city boundaries were extended westwards to include the administrative base and township of Bankipore, known as the New Capital Region. This era also saw the construction of two prominent landmarks, the Patna secretariate and the Patna High Court, designed by architect J.F. Munnings. Many buildings, reflecting either Indo-Saracenic influence or manifesting a Renaissance imprint, were completed by 1916-17. Pseudo-renaissance is expressed in the design of buildings like the General Post Office and the old secretariate. The British also built numerous educational institutions, including Patna College, Science College Patna, Bihar College of Engineering, and Prince Wales Medical College. Patna played a significant role in the Indian struggle for freedom, with notable contributions such as the Champaran Movement against Indigo plantation and the Quit India Movement of 1942.

Post-independence Period

Following India's independence, Patna's economic standing witnessed a sharp decline, particularly in the domain of trade and commerce. The region was predominantly ruled by Congress government from 1947 until the declaration of a state of emergency in 1975. The Bihar movement, led by students such as Jayaprakash Narayan, against the existing maladministration and corruption was initiated in 1974-75, and came to be known as the Sampoorna Kranti, or Total Revolution, and the JP movement. In the year 2000, Bihar faced a severe blow when Jharkhand, a state known for its abundant mineral deposits, was separated from Bihar. This led to a substantial loss in the revenue earned through mining and industrial activities. According to Bhattacharya (2000), while the state has been exploited and left destitute in the past, it could perhaps make up for the loss of mineral deposits by curbing the issue of rampant corruption within its governance structure. In effect, the Freight Equalisation Policy, which involved the transportation of mineral deposits to other states, has resulted in Bihar being underdeveloped. Despite a few challenges encountered during the post-independence, the economy of Patna remained relatively steady until the separation of Jharkhand from Bihar. The present scenario has led to an attempt at rejuvenation and the revitalisation of the region.

Growth

Throughout its history, Patna has experienced growth in various aspects despite its declining status. The earliest known map of the city dates back to 1776, a product of James Rennel for the British-controlled Bihar and Bengal province.

At the time, the city's settlement area was approximately 52 square kilometres. As of 1924, however, the administrative area had expanded by more than double, reaching a total of 142.46 square kilometres. Patna's population has grown more than tenfold since 1901. According to the Statistical Account of Bengal for Patna district in 1877, the city was situated between latitudes 24˚ 58' to 25˚ 42' north and longitudes 84˚ 44' to 86˚ 05' east. The district encompassed an area of 2101 square miles according to the Boundary Commission of 1875. The Census Report of 1872 indicated a population of 15,59,638 for the district (**Fig.** 2).

Spatial Growth

It is challenging task to track the absolute spatial growth of cities in developing nations due to a lack of adequate documentation. During the British period, Azimabad was the main town of Patna, as it was commonly called by the locals. The district of Patna was bounded by the Ganga river in the north, separating it from Tirhut and Saran; Shahabad district lay on the west, separated by the Son river; Monghyr (Munger) lay on the east, and Gaya lay on the south. The settlement and administrative area of Patna has been slowly but steadily expanding. According to toposheet data of Patna from 1924, the settlement covered an area of approximately 52 square kilometres. As per census records in 1961, the administrative area increased to 79.87 sq km (Table-1). The map of the province of Bihar and Bengal (**Fig.** 1) prepared by Major Rennel in 1776 indicates that Patna was an important riverine port city at that time (**Fig.** 3).

Due to this reason, the British colonizers gradually built their separate settlement to the west of the existing settlement. They strategically created military cantonment to protect their interests in trade and power. Britishers had always exploited the resources of Patna without considering the welfare of the city. Buchanan (1812), O'Malley (1907), and Forster (1924) had been critical of the city and its view from a distance was often termed as "mean," "disgusting," "disappointing," and other such derogatory terms. The series of maps for the years 1885, 1924, 1976, and 2009 show the spatial extent of Patna. The map of Patna from 1885 (**Fig.** 1) was prepared by Else Reclus and published in Nations and Nationalities of the World. Although Major Rennel's map does not align with the current system of latitudes and longitudes in modern map-making, it depicts the schematic settlements of Patna at that time. The native settlements mostly confined to the middle of eastern part of the city, between the southern bank of the Ganga in the north and the railway track in the south. Bankipur evolved as the settlement for Britishers, while Danapur cantonment can be seen in the north-western part of the city map.

He Survey of India has performed an outstanding task in mapping the Indian subcontinent's entire terrain in great detail since the British period. These topographical sheets have been invaluable for both military and civilian development purposes. In archives, three distinct toposheets of Patna have been discovered for the years 1924, 1976, and 2009. In 1924, the settlement area was primarily situated along the river Ganga (**Fig.** 2), and the railway line acted as an unofficial southern boundary of the city. Vegetation and water bodies were visibly present in the north-western and central regions, respectively. By 1976, the city had gradually expanded towards the south and south-west (**Fig.** 2), leading to the depletion of vegetation and water bodies during the mentioned period. The nalas of the central zone were severely impacted by the construction of government buildings in that area. The city rapidly expanded towards the west and north-west after 2001, as reflected in the settlement map of 2009 (**Fig.** 2). By this time, the spread of settlements had surpassed the official city limits, providing ample scope for urban sprawl.

Population Growth

Urban studies rely heavily on analysing population growth as a key determinant of the area's land use, infrastructure, and urban amenities. Patna has been a significant urban centre since the British era, as evident from **table-**1. In 1901, the population of the city was 1.8 lakh, which increased to over 2 million in the 2011 census and is expected to exceed 4 million by 2051. However, the rate of population growth has not been constant over time. The 1881 population enumeration recorded a population of 1,70,654, indicating a 7.4% increase of 1,58,900 in nine years. The increase was due to both natural growth and under-enumeration in 1872. In 1901, the population of Patna was 1,80,025. The city experienced stagnant or negative growth during 1911-1921 due to the Bengal famine. The census of 1911 was the last within the state of Bengal, while the 1921 census was the first as the capital city of Bihar and Odisha. Around 12.5 lakh people migrated from Bihar to Bengal in 1911, while around 1.65 lakh people immigrated (**Table-**1).

Post-1921, Patna's population growth fluctuated between 20-40%, indicating steady growth. However, it became a bumpy ride with rapid population growth from 1971-2001. **Table-**1 highlights that the Patna metropolitan city experienced tremendous growth rates in population during 1971-81 and 1991-2001 due to official expansion of the city boundary in adjoining areas. During 1971-81, the PRDA was formed, and three colonies were founded. The outgrowths and adjoining areas of Phulwarisharif, Digha-mainpura, and Danapur cantonment were included in this

agglomeration. During 1981-91, new colonies in Patna gradually expanded in open space within the city limits, which were included in previous official boundary expansion. Prior to the 2001 census, the city boundary was further extended. This time, the expansion was from Didarganj to Sherpur and Bailey road to Saguna more and Danapur junction. Apartment culture was on a boom during 1991-2001. Post-2001, the city boundary has remained unchanged, but the status of towns/outgrowths has been modified, and administrative units have been freshly demarcated during the census of 2011. The adoption of the concept of urban agglomeration dates back to the 1971 census, when it replaced the "town group" category. In the interest of developing plans and changing policies, the Government of Bihar has designated the Patna urban agglomeration as the Patna metropolitan city. Despite this, it was not until 1991, when the population exceeded 1.1 million, that Patna attained the status of a metropolitan area. In the 2001 census, Badalpura was identified as an outgrowth, while Patliputra housing colony and Saidpura were classified as census towns in the 2011 census. Previously, both of these towns had been considered as outgrowths. The expected population of Patna in 2051 is estimated to be around 4.3 million. However, due to its relative power status identity and strategic location,

the city may even exceed 5 million in the near future, largely due to the rapid influx of migrants. Survey results indicate that a significant number of Patna residents have migrated to the city over the past three decades.

Conclusion

The history and evolution of Patna, the capital of Bihar, is a captivating narrative that spans millennia, reflecting the city's deep-rooted cultural, historical, and geographical significance. Its origins are steeped in legend, with various names and tales that narrate its evolution from a small village named after the patli flower to the flourishing capital of the Mauryan Empire. This historical tapestry weaves folklore, divine intervention, and urban genesis into the fabric of Patna's identity. Megasthenes described the city as being located on the southern bank of the Ganges, at the confluence of the Son river which once joined the Ganges below present-day Patna. Memories of this junction still exist amongst the villagers to the southwest of Patna, where an old channel named the Mara Son flows. As time progressed, the city underwent significant changes, from the Mauryan period to the Shershah Suri era, ultimately becoming an essential strategic and trade centre for the British. The modern Patna has expanded exponentially since British times. Post-independence, the city faced economic challenges, and the separation of Jharkhand in 2000 led to a decline in revenue from mining and industrial activities. With the exponential growth in population and physical expansion of the city, the local administration is tasked with the challenge of providing basic urban amenities and maintaining the city's infrastructure. As the city continues to receive migrants from other areas, there is a shift in the land-use and land-cover patterns, resulting in urban sprawl beyond the city limits.

Between 1924 and 2022, the Patna metropolis has undergone a nearly threefold expansion, specifically from 51.46 to 142 square kilometres. Correspondingly, the demographic landscape has witnessed significant growth, with the city's population escalating substantially from 1.8 lakh in 1901 to 20.5 lakh in 2011. However, notwithstanding these pronounced spatial and demographic advancements, the city exhibits a deficiency in terms of fundamental industrialization. As Patna looks towards the future, it is poised for further growth and development, with its strategic location and historical significance continuing to shape its trajectory. The city's journey from ancient legends to a modern metropolis underscores its resilience, adaptability, and enduring importance in the cultural and historical landscape of India.

BIOLOGIC EFFECTS OF INGESTION OF NITRATE IN DRINKING WATER AN OVERVIEW OF INDIA

Narender Singh, Dr. Ranjeet Kumar and Prof. Tribhuvan Prasad

Abstract

Nitrate pollution in surface or subterranean water is a pervasive global issue, particularly prevalent in agrarian nations. Undoubtedly, regions most susceptible to climatic shifts face heightened vulnerability owing to their geographical disposition. Unfavorable topographic features and uncertainties in hydro-meteorological conditions amplify the extent of contamination. Given that nitrate pollution in our potable water sources is pandemic and the costs linked to purifying these water sources are exorbitant, exposure to elevated nitrate levels significantly contributes to deleterious health consequences that necessitate attention. This manuscript delves into the biological ramifications of surplus nitrate in our drinking water and the diverse array of human health concerns in India and various pivotal parts of the globe. In a bid to forestall methemoglobinemia, an acute toxic response to nitrite exposure impeding oxygen transport via the bloodstream, the US EPA (Environmental Protection Agency) has designated the maximum admissible nitrate level in drinking water at 10 mg nitrate-N/L. However, it's a common occurrence for surface and subterranean water in agricultural regions to surpass this standard periodically and/or over extended durations. While a definitive correlation between nitrate consumption and cancer remains elusive, some indications suggest a potential linkage. The magnitude of health risks posed by nitrate contamination in drinking water remains a subject of debate. Groundwater stands as a vital water source for both domestic and agricultural usage on a global scale. It serves as the primary domestic water source for 50% of the world's populace and nearly 90% of rural inhabitants. A substantial 75-80% of water used for agricultural irrigation originates from groundwater. Safeguarding groundwater against nitrate pollution presents a multifaceted managerial challenge necessitating effective policy alignment at federal, state, and local echelons, particularly due to the inherent complexity of groundwater purification. Moreover, these challenges are compounded by varying levels of awareness, socio-economic development, low literacy rates, high poverty, and the inclusion of cultural practices and rituals, all of which exacerbate the intricacies of the endeavor.

Introduction

Ensuring safe drinking water remains crucial for public health, a fundamental human entitlement. Regrettably, this right falls short of people's expectations. Water, an essential element, faces an impending challenge as research indicates an upward trajectory in nitrate levels. This concern extends beyond rural communities, impacting major urban centers reliant on bore water. The solubility and biodegradability of nitrates contribute significantly to their increased presence in water bodies. The consequential decline in both quality and quantity of water bodies persists due to the heavy reliance on synthetic fertilizers, sewage, industrial waste, and livestock manure. Guidelines from the US EPA's nutrient data policy reveal the distinct markers of nitrate presence. While nitrates occur naturally at very low levels (<1mg/L NO3-N), levels exceeding 1mg/L NO3-N are indicative of human activities. Concentrations surpassing 3mg/L NO3-N generally signal groundwater contamination. In India, the Bureau of Indian Standard (BIS) stipulates the Maximum Contaminant Level (MCL) for nitrate in public drinking water supplies at 45 mg/L as nitrate (NO3-), nearly akin to the WHO guideline of 50 mg/L as NO3- or 11.3 mg/L NO3-N (derived by multiplying NO3 mg/L by 0.2258).

Interestingly, this MCL, initially set in 1962 by the US EPA to prevent infant Methemoglobinemia, lacks considerations for other potential health impacts. A crucial issue with the current MCL for nitrate in drinking water is its obsolescence, particularly its lack of association with colorectal cancer, thyroid ailments, or neural tube defects. Consequently, a more lenient limit of less than 10mg/L NO3-N was established as a generalized threshold for nitrate contamination, offering a lax aspiration level within this range. This distinction between actual safety and mere cleanliness holds immense significance. It delineates a fine line between life and death, between improved health and the burden of costly medical bills for young families, and between mere survival and flourishing for entire communities. Nitrate, prevalent in various foods, peaks in green leafy vegetables like spinach and celery, as well as root vegetables such as beetroot. Daily intakes from food range from 30-130 mg/day as NO3- (7–29 mg/day NO3-N) (ICAR, 2020). Once consumed, most of the ingested nitrate travels through the body and is absorbed into the bloodstream via the small intestine. Approximately 25% of the nitrate in the blood is transformed into nitrite through a reduction process in saliva. While most nitrite is absorbed into the blood and converted into beneficial compounds, a fraction may form potentially harmful N-nitroso compounds.

Study Region

Indeed, nitrate pollution stands as one of the oldest and most financially burden some environmental issues, both regionally (India) and globally. Several contributing factors underline this reality: A notable surge in population, from 5.3 billion to 7.7 billion between 1990 and 2020, with projections foreseeing a rise to 9.7 billion by 2050 (UN, 2020). The onset of increased industrial activities since the mid-19th century has significantly amplified pollution and deterioration of water resources (Bond et al., 2018). Climate change exacerbates water stress globally, particularly in arid regions, through diminished rainfall, leading to severe droughts and erratic rainfall patterns during the rainy seasons (Lorite et al., 2018; WHO, 2012). In recent years, ensuring access to clean drinking water for communities has become increasingly challenging due to the emergence of new water quality issues. Groundwater sources, vital for global agri-businesses, industries, and drinking water needs, face mounting pressure amid growing scarcity concerns and fears of microbial contamination. Nitrate contamination, prevalent in agricultural and densely populated regions, notably affects the Indo-Gangetic Plain (IGP), recognized as one of the world's largest alluvial aquifer systems (MacDonald et al., 2016). Spanning approximately 52 million hectares, it supports a population of 500 million across Delhi, Haryana, Punjab, Bihar, Uttar Pradesh, and West Bengal according to the 2011 Census.

The northwestern segment, marked by intensive agricultural practices and widespread nitrogen-based fertilizer use, exhibits significant groundwater contamination hotspots. India grapples with 20 identified nitrate hotspot areas, each displaying varying average nitrate levels. Some regions indicate averages below 50 ppm, while others range between 59 and 215 mg/L, showcasing considerable data variability (Devaraj et al., 2020; Pant et al., 2020). Notably, values surpassing four times the WHO-recommended standard are reported in certain areas, such as Birbum in West Bengal (44 & 45), Solapur in Maharashtra (66 & 71), and Bareilly in Uttar Pradesh (31 & 51), with reported average values spanning from 7 to 47 mg/L. Even within these regions, over a quarter of samples exhibit nitrate concentrations exceeding 50 mg/L (Hossain & Patra, 2020; Mazhar & Ahmad, 2020; Mukate et al., 2019). The causes of pollution in the country are attributed to various factors, including inadequate maintenance of septic tanks, boreholes, sanitation, and fertilizer use, as highlighted by several authors (Barbieri et al., 2019; Devaraj et al., 2020; Roy et al., 2020).

Objectives

(1) This study aims to conduct a health risk assessment of nitrate in distributed drinking water in India and across significant global regions.

(2) Assessing what needs to be done to ensure an adequate drinking water supply throughout the country & what can be done in managing land & water to limit nitrate pollution.

Database and Methodology

The interest in studying groundwater health, particularly concerning nitrates, has seen a significant surge since the early 1980s. From an average of 100 articles per year globally in the 1970s and 1980s, the scientific community published 2742 articles in 2020 on this subject. In India, the Integrated Management Information System (IMIS) was established in 2009 alongside the National Rural Drinking Water Programme (NRDWP), creating a web-based platform for annual online monitoring of water supply projects and rural coverage. Sarkar et al. (2021) investigated the spatial variation of nitrate content in Indian groundwater using data from the NRDWP database. Various studies nationwide have sampled groundwater from wells, boreholes, and springs primarily used for irrigation or domestic purposes (Devaraj et al., 2020; Hossain and Patra, 2020; Mazhar and Ahmad, 2020; Mukate et al., 2019). However, several nitrate-contaminated areas, particularly within the Indo-Gangetic Plain, were not adequately covered in individual studies, posing a significant limitation. Larger-scale or national studies are necessary to comprehend the extent, spatial distribution, sources, and health impacts of groundwater nitrate contamination, mandating efficient local governance and management. Yet, a comprehensive detailed interpretation required for this remains lacking. Despite numerous articles published until December 2021 detailing groundwater quality parameters, a comprehensive understanding of nitrate pollution and its health impacts at the local level remains elusive. Conducting a comprehensive research and assessment of the health effects of groundwater nitrate contamination at the local level is a novel undertaking. This review delves into nitrate sources in groundwater, its health implications, and focuses on human health risk assessment. Such a study is pivotal in understanding the challenges India faces in achieving Sustainable Development Goals (SDGs) 6.3 outlined by the United Nations in 2015.

Result and Discussion

Methemoglobinemia

Methemoglobinemia, linked to elevated nitrate levels in drinking water used for infant formula preparation, was initially documented in 1945 (Comly H.H. et al., 1945). When ingested, bacteria in the mouth and the less acidic infant stomach convert nitrate to nitrite. Nitrite, in turn, binds with hemoglobin, forming methemoglobin, which disrupts the blood's capacity to carry oxygen. Methemoglobinemia is a severe condition, posing a life-threatening risk when methemoglobin levels exceed approximately >10 mg/L NO3-N. Risk factors for infant methemoglobinemia encompass formula prepared with water containing high nitrate levels, along with foods, medications, and enteric infections that exhibit high nitrate levels. non-existent in these areas.

Adverse reproductive outcomes: (spontaneous abortions)

There have been several studies examining spontaneous abortions, linking high maternal methemoglobin levels caused by elevated nitrate ingestion to miscarriages in laboratory animals and livestock. An intriguing 1996 Center for Disease Control (CDC) of Morbidity and Mortality Weekly Report (MMWR) report documented a cluster of spontaneous abortions among women using private wells in rural Indiana, where nitrate levels exceeded twice the Maximum Contaminant Level (MCL) of 20 mg/L NO3-N. When these women switched to low-nitrate water sources, they experienced healthy live births. While this wasn't a formal study, the evidence was compelling, suggesting the involvement of high-nitrate water in the miscarriages. Interestingly, a separate study in Massachusetts found no association between spontaneous abortion and lower nitrate levels below 5.5 mg/L NO3-N, indicating divergent findings in different settings Indeed, there's been documentation of a heightened incidence of infant methemoglobinemia in Eastern Europe, as noted previously (Ayebo A. et al., 1997). A 2002 WHO report on water and health highlighted significant cases in the region: 41 cases annually in Hungary, 2913 cases in Romania spanning 1985–1996, and 46 cases in Albania in 1996. Generally, nitrate levels surpassing >10 mg/L NO3-N were often linked to increased methemoglobin levels, though clinical methemoglobinemia wasn't consistently present (Fig-1). In India, methemoglobinemia is relatively uncommon, possibly owing to limited awareness or a scarcity of epidemiological studies on the disease. It's intriguing that in a country where agriculture is a predominant livelihood and where sanitation remains inadequate in numerous regions, reported instances of methemoglobinemia are rare (**Fig.** 1).

Birth Defects and Cancers

According to a 1995 IARC report, over 300 nitroso compounds were tested in animals, with about 90% found to be carcinogenic. These compounds showed carcinogenicity across various animal species, including non-human primates, suggesting a likelihood of impact on humans. These nitroso compounds have the potential to induce tumors in multiple organs such as the lungs, digestive tract, urinary tract, and some reproductive organs. Exposure during pregnancy can lead to congenital malformations, particularly affecting the Central Nervous System, especially during the critical phase of organ development in the first trimester. Shifting focus to cancer, in 2006, an IARC working group assessed the evidence for the carcinogenicity of ingested nitrate and nitrite. Their conclusion stated that under conditions conducive to the formation of N-nitroso compounds or endogenous nitrosation, nitrate and nitrite were deemed probably carcinogenic to humans. The evaluation drew from compelling evidence obtained through animal studies, where carcinogenicity was consistently observed across all species tested in laboratory settings. Additionally, human mechanistic studies provided further support. These studies indicated that exposure to nitrosamine compounds increased with nitrate ingestion, either through drinking water or controlled intake experiments. It was demonstrated that nitrate ingestion led to heightened exposure to nitroso compounds, measured by their excretion in urine. This correlation between nitrate intake and increased presence of these compounds provided robust evidence supporting the evaluation's conclusions.

Case-control or Cohort Studies of Drinking Water Nitrate and Cancer Studies

(1) Colorectal:5 studies (4 Positives)
(2) Brain(Children/young adults):3 studies (3 Positives)
(3) Bladder:4 studies (2 Positives)
(4) Kidney: 2 studies (2 Positives)
(5) Non–Hodgkinlymphoma:3 studies (1 Positives)
(6) Pancreas: 2 studies (0 Positives)
(7) Brain (adults): 2 studies (0 Positives)

In terms of epidemiological studies, investigations into dietary nitrate consumption didn't yield any association with an increased risk of cancer. However, when it comes to drinking water, the evidence was deemed inadequate due to the limited number of studies available.

Presently, the strongest evidence from epidemiological research suggests a positive association between nitrate exposure and colorectal cancer, with four out of five studies demonstrating such a link. Similarly, concerning childhood brain tumors (including young adults in one study), all three available studies indicate a positive association, with two of these studies conducted or published within the past year. However, for other cancer sites, there's notably less evidence available.

Nitrate in Drinking Water and Hypothyroidism:

In terms of biological plausibility, the concern doesn't solely revolve around nitroso compounds, but also involves nitrate's potential to impede iodine uptake by the thyroid. Three studies showed positive associations between higher water nitrate ingestion and related health issues: A study conducted on school-age children in Slovakia revealed an increased prevalence of subclinical hypothyroidism in areas with high water nitrate levels (ranging from 51 to 274 mg/L NO3-) compared to areas with nitrate levels at or below 50 mg/L (11 mg/L NO3-N) in water supplies (Tajtakova M. et al., 2006). A cohort study of post-menopausal women in Iowa found that higher nitrate intake, both through diet and drinking water from Public Water Supplies, was linked to an increased prevalence of hypothyroidism (Ward M.H. et al., 2010). An Amish cohort study in Pennsylvania discovered that among women, but not men, higher water nitrate levels (>6 mg/L NO3-N) were associated with elevated thyroid stimulating hormone (TSH) levels and a greater prevalence of subclinical hypothyroidism (Aschebrook-Kilfoy B. et al., 2012).

The primary human-caused sources of nitrate contamination fall into five categories: septic tanks, sewage, agriculture, landfills, and industrial activities. Often, nitrate pollution occurs alongside contamination by fluorine, sulphates, potash, phosphates, and heavy metals like zinc, cadmium, or arsenic. This pollution is frequently concentrated in areas reliant on agriculture for income or where sanitation infrastructure is lacking. Beyond these sources, various catastrophic events in recent decades have altered nitrate levels in groundwater in affected regions. For instance: The groundwater near the Union Carbide factory in Bhopal has faced excessive nitrate, chloride, and heavy metal contamination. ("Water Contamination Crisis - Bhopal's Second Disaster - The Bhopal medical appeal", 2021) The Beirut explosion in 2020, caused by inadequate storage of 2750 tons of ammonium nitrate, released a substantial amount of pollutants into the environment. Following the Chernobyl accident, two regions in Belarus reported similar radiation levels, yet the incidence of pediatric thyroid cancer differed significantly due to variations in nitrate contamination in drinking water, measuring 40 vs. 185 ppm (Drozd et al., 2018).

This escalating pollution trend requires immediate and drastic solutions to prevent further degradation of natural water bodies, particularly in developing countries like India, where water shortages exacerbate the issue. Urgent actions are essential to avert the complete deterioration of these vital water resources.

Conclusion

This review examines the water quality of various groundwater bodies throughout the country in terms of nitrate concentrations, discusses various health issues for both this compound and other important pollutants. On the basis of which some general conclusions can be drawn.(1) The occurrence of nitrates in groundwater continues to increase and urgent measures are therefore required to prevent nitrates from breaking down into water particles. (2) Levels exceeding the WHO standard (50 ppm) exist in various parts throughout the country. (3) Nitrate pollution from agriculture, especially the use of fertilizers and pesticides, is common across the nation. (4) In India, large fluctuations in NO3- concentration are observed due to the strong influence of the rainy season and insufficient treatment of septic tanks. (5) In addition to pollution from fertilizers, wastewater discharged without proper treatment & industrial activities contribute significantly to the occurrence of nitrates in groundwater. (6) Apart from the various reasons summarized above, environmental pollution is mainly due to poor health conditions in many parts of India (e.g. the presence of untreated septic tanks). Currently, there are many surface water treatment facilities, but the number of groundwater treatment facilities is still very limited and further research is needed into different treatments for nitrate removal. Recent studies on cancer and birth defects have started identifying population subsets prone to internal nitrosation, but direct methods for identifying these individuals are necessary. New approaches in epidemiological research, such as detecting nitrate-reducing bacteria in the oral micro biome and studying genetic variations in nitroso compound metabolism, hold promise in identifying high-risk individuals. However, a lack of comprehensive studies on individual health impacts hampers definitive conclusions about the risks of consuming nitrates through drinking water. Further investigation is crucial, especially in refining exposure assessment for users of public water systems, understanding exposure levels among those using private wells, quantifying nitrate-reducing bacteria, and assessing various factors influencing nitrosation. Focusing on conditions like colorectal cancer, thyroid disease, and central nervous system birth disorders, consistently associated with nitrate ingestion from water, will significantly contribute to clarifying these concerns.

A GEOGRAPHICAL ANALYSIS OF CROP CONCENTRATION IN PRAYAGRAJ DISTRICT

Neha Yadav and Dr. Sangeeta Chauhan

Abstract

This study focuses on analyzing crop concentration in Prayagraj District, encompassing all 20 blocks. Secondary data from the year 2020-21 was utilized for this research. Crop concentration is crucial in understanding the suitability of specific areas for particular crops, particularly considering changes in agricultural land use and shifts in crop proportions. Crop concentration has been determined using the Bhatia's location quotient technique. This technique identifies changes in agricultural land use by examining shifts in the proportion of land allocated to various crops. The study calculated the amount of area involved in these changes, highlighting the crops with the most significant increases and decreases. The data obtained is used to create thematic maps, providing a spatial representation of crop concentration in the district. Crop concentration is categorized into four sections: High, Medium High, Medium and low. These categories help depict the intensity of land utilization and identify areas suitable for specific crops. One significant determinant of cropping patterns is irrigation, which generally has a positive influence on the intensity of cropping. The study observed substantial variations in land use and cropping patterns across the study area. Wheat and Rice emerged as the dominant crop throughout the district, in terms of total agricultural production. This research sheds light on the changing cropping patterns and land utilization in Prayagraj District, providing valuable insights into the suitability of different areas for various crops. The findings can inform agricultural planning and land-use policies in the region, helping optimize crop production and land utilization.

Introduction

Crop concentration, as defined by TS Chauhan in 1987, pertains to the spatial distribution of individual crops within a specific area. It serves as an indicator, revealing the variability in crop density within a given region at a particular moment in time.

The delineation of crop concentration assumes paramount importance in the realm of agricultural planning and development. The cropping pattern observed in any region is intricately woven with a tapestry of influences, including geo-climatic, socio-economic, historical, and political factors, as noted by M. Hussain in 1996. Moreover, technological factors have emerged as influential forces shaping these patterns. Terrain, topography, slope, soil composition, and the presence of irrigation facilities all contribute to the diversity of cropping patterns. The use of pesticides, fertilizers, and mechanization further compounds these complexities. Understanding the myriad factors that influence cropping patterns, from natural elements to human interventions, is fundamental for effective agricultural planning and development. The various geographers applied location quotient methods to work out the degree of Crop Concentration in a specific region. The geographers pioneer work of Chisholm (1962), Bhatia (1965), Jasbir Singh (1976) are the contributors to make the agricultural region with the help of quotient method. In this research work, Bhatia's method has been adopted to measure the index of Crop Concentration in Prayagraj District.

Study Region

Latitudinal and longitudinal extent of Prayagraj District is 24°47' N to 25°45'N and 81°31'E to 82°21'E in the south of Uttar Pradesh State at an elevation of 98 meter (322 Ft) and is situated at the confluence of Ganga and Yamuna. To its south and southeast is the Baghelkhand region, to its east is middle Ganges valley of North India, to its southwest is the Bundelkhand region, to its north and northeast is the Awadh region and to its west along with Kaushambi it forms the part of doab i.e. the lower doab region. Prayagraj has a humid subtropical climate. It experiences three seasons in a year. The summer lasts from April to June, monsoon begins in in early July and lasts till September, and the winter season lasts from December to February. The Ganga and Yamuna are the main rivers of the district. The plain area of the district is situated in between Ganga and Yamuna so these rivers play a very pivotal role in the agriculture of the district. The main staple crop of Prayagraj is wheat and rice. According to 2011 census, population of the study area is 5,954,391 of which male and female were 3,13,807 and 2,822,584 respectively. Population growth rate was 20.63% compared to 2001 census. The headquarter of the district is Allahabad City. The district is divided into blocks and tehsils. As of 2011 census there are 20 blocks in 8 tehsils. The total area of the district is 5,482 sq. km. The number of villages is 3003 according to Prayagraj statistical bulletin.

Objectives

(1) To analyze the crop concentration and its variation in Prayagraj District.

(2) To identify the areas of crop concentration in the basis of Bhatia's method.

Database and Methodology

The research work is based on the secondary data obtained from UP statistical Bulletin, Prayagraj (2020-21). Various thematic maps related to cropping patterns are prepared with the help of GIS. In order to determine block wise crop concentration Bhatia's method has been used.

Crop Concentration Index: = (a/b)/(A/B)

Whereas:

a= area of crop 'a' in the component areal unit

b= area of all the crops in the component areal unit

A= area of crop 'a' in the entire region

B= area of all crops in the entire region

Here, the higher index values represent a high level of crop concentration and low values show the low concentration of crop

Crop Concentration Pattern

Rice: It is a staple crop that serves as a primary food source for more than half of the world's population. Paddy is the second most important food grain in Prayagraj district it is cultivated in the kharif season. Moderate temperature and high rainfall is required for its cultivation. Rice cultivation supports the livelihoods of millions of farmers worldwide, it is a source of income and employment for rural communities. Rice is a major agricultural commodity in international trade, contributing significantly to the economies of exporting countries. In 2020- 21, total area under paddy cultivation was 155655 hectares. Paddy is cultivated in all the blocks of Prayagraj district. The blocks having medium high concentration of paddy are Jasra, Shankargarh, Meja, Manda, Holagarh, Mauaima, Soraon, Phulpur Pratappur and Dhanupur. Rest of the blocks have medium concentration of rice. Medium high concentration is in the northern and southern regions of the study area except Koraon and medium concentration is in the centre of the district.

Wheat: Wheat is the most important crop in Prayagraj. It is a Rabi crop it requires cool temperature and moderate rainfall, wheat is harvested in the summer

Table-1: Crop Concentration Index of Rabi Crops in Prayagraj District

Blocks	Crop Concentration Index 2020-21

Source: Calculated and compiled by Authors.

when the grains have fully developed and turned golden brown, modern machinery such as combine harvesters is used for efficient harvesting. Wheat is a primary source of carbohydrates for a significant portion of the world's population. It is a staple food in many countries and is used to make a wide variety of products, including bread, pasta etc (**Table-**1). Wheat is a fundamental component of the world's food

supply. Reliable wheat harvests help stabilize food prices and ensure a consistent food supply enhancing global food security, therefore good concentration of wheat is very crucial for famer and other people. The total area under wheat cultivation in 2020-21 was 249902 hectares. Blocks having medium high concentration are Phulpur, Pratappur, Handia, Jasra, kaundhiyara, Meja and rest of the blocks have medium concentration. Medium high concentration is in the south and north east in Prayagraj District and medium concentration is in the northwest of the study area (Fig-1).

Barley: Barley holds significant importance due to its various uses and nutritional benefits, it is rich in dietary fiber, vitamins and minerals and has low glycemic index. Farmers often cultivate barley for both human consumption and livestock feed, enhancing agricultural productivity. In Prayagraj barley is grown in winter season. In Prayagraj total area under Barley is 2062 hectares (2020-21). In the district blocks having high concentration are Bahadurpur, Chaka Karchhana, Uruwa and Manda the block having medium high concentration are Kaudihar, Saidabad, Handia and blocks having medium concentration are Soraon, Pratappur, Dhanupur, Shankargarh, Meja and Koraon. Rest of the blocks have low concentration.

Vegetables: The vegetables grown in Rabi season are tomato, potato, onion, cauliflower spinach, radish green peas etc. The blocks having high concentration of these vegetables are Holagarh, Mauaima, Kaudihar, Baharia, Soraon, Pratappur, Saidabad, Dhanupur, Handia, Chaka and the block having medium high concentration of Rabi vegetables is Bahadurpur. Rest of the blocks have low concentration. The vegetables grown in Kharif season are bitter gourd, bottle gourd, brinjal, green beans, sponge gourd etc. Blocks having high concentration are Kandahar, Holograph, Bahrain, Manama, and Soprano. The blocks having Medium High concentration are Philpot, Pratappur, Bahadurpur, and Handia. Blocks having medium concentration are Dhanupur, Chaka. Rest of the blocks have low concentration.

Sorghum: Sorghum, also known as jowar in India, is a versatile cereal crop that holds significant importance in the country. Sorghum is drought- resistant, making it crucial crop in regions prone to water scarcity. It can withstand harsh weather conditions, ensuring food security in arid and semi-arid regions. This is a kharif crop, the blocks having high concentration are Shankargarh, Meja, Uruwa, Chaka, Karaon and Meja, the block having medium high concentration is Handia. Mauaima and soraon have zero concentration of Sorghum. Bahadurpur, Pratappur, Saidabad, Dhanupur, Jasra, Kaundhiyara and Manda have medium concentration, rest of the blocks of low concentration (**Table-**2).

Table-2: Crop Concentration Index of Kharif Crops in Prayagraj District

Blocks	Crop Concentration Index 2020-21									
	Rice	Sorghum	Pearl Millet	Maize	Urad	Pigeon Pea	Sugarcane	Sesame	Vegetables	Fodder

Source: Computed by Authors

Pearl Millet: Pearl millet is known as Bajra in India. Bajra is rich in protein, fiber, vitamins, and minerals, making it a valuable dietary staple, especially in regions with poor soil quality and limited access to other nutritious food. This is also a drought resistant crop, many small scale farmers rely on bajra cultivation for their subsistence, providing a source of income and sustenance for their families. This is grown in kharif season the blocks having high concentration are Soraon,

Fig. 1

Bahadurpur, Karchhana, Saidabad, Kaudihar, Baharia and Uruwa. The blocks having medium high concentration are Handia and Chaka. Meja has medium concentration of Pearl millet, rest of the blocks have low concentration.

Maize: Maize is a staple food for millions of people in India. It is consumed in various forms, such as corn on the cob, popcorn, and makki di roti. This is a droght resistant crop making it suitable for cultivation in regions with irregular rainfall patterns. Maize crop yields a high quantity of grains per hectare, contributing to agricultural productivity. It is grown by both small scale farmers and commercial agricultural enterprises. In Prayagraj, Maize is grown in kharif season, this is rainfed crop, Pratappur, Saidabad, Dhanupur, Handia and Koraon have high concentration of maize. Holagarh has medium high concentration. Baharia, Phoolpur and Manda have medium concentration.

Pulses: Pulses are a primary source of protein for millions of vegetarians in India. They are essential for fulfilling the protein requirements of a predominantly vegetarian population. The pulse industry creates employment opportunities in rural areas, including processing, trading, and transportation, contributing to the rural economy. Pulses cultivated in Prayagraj are Urad, Arhar, Masoor and Chana, the most important among them is Arhar or Pigeon Pea. Arhar dal requires a warm and tropical climate, moderate and well distributed rainfall, well-drained soil, abundant sunlight, and careful management of pests and diseases. The total area under arhar is 14639 hectares (2020-21). Chaka, Karchana and Koraon have high concentration. The blocks Jasra and Uruwa have medium high concentration. Kaudihar, Handia, Saidabad Shankargarh, Kaundhiyara, Meja and Manda have medium concentration. Rest of the blocks have low concentration. Out of 20, 7 blocks have medium concentration of Arhar in Prayagraj District.

Sugarcane: Sugarcane is the primary source of sugar production in India. Sugarcane cultivation and the sugar industry contribute significantly to the Indian economy. India is one of the largest producers of sugarcane and sugar in the world. Sugarcane farming provides employment to millions of farmers and labourers, especially in rural areas. Sugarcane is a long duration crop and requires 10 to 14 months to mature depending upon the geo- climatic conditions, it require 75 to 150 cm rainfall and in average 21 degree to 27° C temperature for better growth in 2020-21 total area under sugarcane cultivation was 666 hectares, the blocks Karchhana, Dhanupur, Pratappur and Mauaima have high concentration. Soraon, Phulpur, Handia have medium high concentration. There is no cultivation of sugarcane in Shankargarh, Chaka and Jasra. Baharia, Kaundhiyara and

Manda have medium concentration. Rest of the blocks have low concentration index of sugarcane in Prayagraj District.

Oilseeds: The most important oil seed in Prayagraj district is mustard. This is usually sown in the winter season from October to December, mustard prefers cool and dry weather during its growth period. Moderately drought resistant but requires adequate moisture during its early stages. The blocks having high crop concentration are Karchhana, Chaka and Koraon. The block having medium high concentration are Bahadurpur, Jasra and Meja. Rest of the blocks have low concentration of mustard crop. Other oilseeds grown in the district are Sesame and Flaxseeds. Sesame is cultivated in all the blocks of the district while flaxseed is cultivated only in 8 blocks of the district.

Fodder: The choice of fodder crop depends upon climate soil type and livestock requirements. For any region fodder plays a crucial role in supporting the livestock population. Fodder is crucial for dairy farming. Well-nourished dairy animals produce higher quantities of milk, supporting the dairy industry and ensuring a regular supply of milk and dairy products for consumers. In the district most of the fodder is grown in kharif season covering 2753 hectares (2020-21) of the total crop area. Two blocks have high concentration, they are Bahadurpur and Handia. The blocks having medium high concentration are Kaudihar, Soraon, Phulpur, Pratappur, Saidabad, Dhanupur, Shankargarh and Manda. The blocks Holagarh, Baharia, Karchhana, Uruwa and Koraon have medium concentration, rest of the blocks have low concentration. Crop concentration index of fodder in the blocks are mostly in medium high and medium range.

Conclusion

The variations in the concentration of Crop cultivation across the study region can be attributed to a complex interplay of factors, including geographical features, climate, water resources, socio-economic conditions and technological influences. These factors collectively contribute to the special distribution pattern of crops in the area. According to research analysis there is not much difference in crop concentration pattern of rice and wheat in the blocks of Prayagraj, this can be attributed to almost similar physical features across the district. High concentration of Barley can be seen in the centre of Prayagraj, only the 25% of the total production of Barley is irrigated. High and medium high concentration of vegetation of both Rabi season and Kharif season is in the Northern portion of the district. Medium high concentration of Sorghum is in the southern portion of the district,

it is a completely rainfed crop. High concentration of sugarcane is observed in east of the district and in Mauaima block which is in northern region of Prayagraj. High concentration of mustard is observed in the centre of the district in northwest and in southern block (Koraon). We can observe that crops like wheat and rice have almost even concentration and the other crops like barley, sorghum, pearl millet, maize, pulses, sugarcane and oilseeds have uneven distribution. This is because wheat and rice is the staple crop of Prayagraj which supports them financially and provides sustenance and other crops are cultivated by the choice of farmers where they have favorable conditions.

SOCIO-ECONOMIC STATUS OF THE VANTANGIYA COMMUNITY: A CASE STUDY OF VANTANGIYA VILLAGES IN MITHAURA BLOCK OF MAHARAJGANJ DISTRICT

Ruchika Singh and Vaibhav Tripathi

Abstract

The Vantangiya community is a community based on economic activities, which the Britishers settled between the 1920s and 1930s to plant and protect Sal and Teak trees in the Terai areas of the states of Uttar Pradesh and Uttarakhand to meet their economic and infrastructural needs. Since the beginning, the people of this community have been living a displaced life; they were displaced from one place to another in an interval of about five years to plant and protect trees like bonded labours. More or less, this situation remained the same even after the country got independence. The Vantangiya community has been a victim of socio-economic deprivation for many years, and they have struggled a lot to get their rights. The current study examines the socio-economic status of the Vantangiya community in the Mithaura block of Maharajganj district. Socio-economic status of the different villages of the Vantangiya community was identified using the Socio-Economic Index which was constructed by the composition of various socio-economic factors like health, demographic characteristics, education, income-expenditure ratio, land ownership, etc. Variables of all these socio-economic factors and their values are pre-assumed and the value of Standard Socio-Economic Index (SEI) has been calculated on the basis of standard values of all these variables. Based on the value of the Standard Socio-Economic Index, a comparative analysis of the socio-economic status of the five villages of the Vantangiya community is analysed in this study.

Introduction

"Socio-economic development is a process of quantitative, qualitative and structural changes that are a result of actions of subjects taken within social(economic) practice. These changes influence life conditions in the following fields: material conditions (possibility to satisfy needs associated with consumption

of goods and services; it is related with the phenomena of economic growth), economic structure and entrepreneurship, access to public goods and services (that results in changes of education level, a way of taking care of someone's health etc.), relation within social system (integration between individuals, trust, security, social conflicts), environment condition and life satisfaction." Its goal is to maintain the region and its people's social and material well-being in order to achieve the optimal level of human development. Development, in the socio-economic context, refers to the improvement of people's standard of living through better employment, income, skills, and development opportunities. Thus, socio-economic development is the process by which a society develops both socially and economically. Health care facilities, sanitization, the availability of clean water, literacy, the income-to-expenditure ratio, and land ownership are some indicators used to measure it. A person's or group's socio-economic status is a combined economic and social measure of their position about others based on their health, education, and occupation. Socio-Economic status consistently and accurately predicts a wide range of outcomes throughout a person's life. A community is a social group that shares common things like area, traditions, beliefs, values, and identity. Communities may share a sense of place in a specific geographic area (like a country, hamlet, town, or neighbourhood) or virtual space through many communication platforms. According to the given definition of community, a community developed based on economic activities in the state of Uttar Pradesh and Uttarakhand of India in the first half of the 20th century is called the Vantangiya Community. Natural forests were extensively cleared for railway tracks some 100 years ago in this region when India was ruled by the British. Based on the Tangiya technique, a farming strategy used in the mountains of Myanmar, the British chose to create a forested area in its place. Many labourers were brought to the forest for this purpose from the villages of the Gorakhpur division. As a result, they were given the name "Vantangiyas"; "Van" signifies forest, and "Tangiya" comes from the words "tongya" where "tong" means mountain and "ya" belongs to the agricultural area. In Uttar Pradesh and Uttarakhand, the Tangiya system was implemented between 1920 and 1923. More than 5,000 Vantangiya families live in 23 forest villages in Gorakhpur and Maharajganj districts. Since the beginning, the people of this community have been living a displaced life; they were displaced from one place to another in an interval of about five years to plant and protect trees like bonded laborers. More or less, this situation remained the same even after the country got independence. The Vantangiya community has been a victim

of socio-economic deprivation for many years, and they have struggled a lot to get their rights. Due to the prohibition on their primary economic activities for the past several decades, they were forced to lead a displaced life, but for some years, through governmental and non-governmental efforts.

Study Region

Maharajganj district is situated north-eastern Tarai part of Uttar Pradesh in India. Its boundaries touch Nepal Estate in the north, Gorakhpur district in the south, Kushinagar district in the east, and Siddharth Nagar and Sant Kabir Nagar districts in the west. The total area of this district is 2952 square kilometers. Based on the census of 2011, the total population of this district is 26,85,292. Maharajganj was a tahsil of Gorakhpur and became a district on 2 October 1989. Maharajganj district consists of 12 Vikas khand blocks- Partawal, Paniwara, Pharenda, Dhani, Brijmanganj, Nautanwa, Lakshmipur, Mithaura, Nichlaul, Siswa Bazar, Ghughuli & Maharajganj Sadar. Vantangiya community lives in different blocks of the district in which Mithaura block takes prominent place where 5 Vantangiya villages are located: Baluahiya, Hathiahwa, 24 Nursery, 27 Nursery and 28 Nursery. The current study deals with the socio-economic status of these villages.

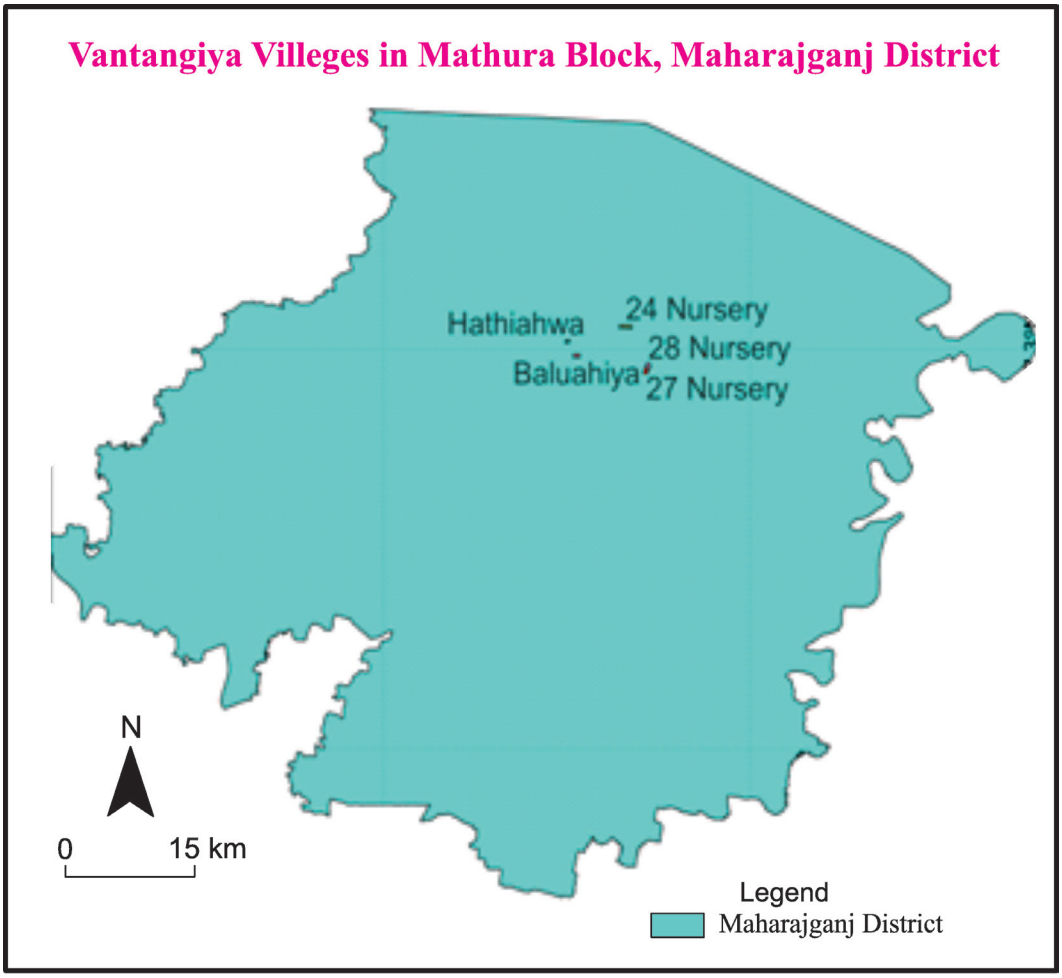
Objective

The main objective of the current study is to analyse the socio-economic status of the Vantangiya community in the Vantangiya villages of Mithaura block of Maharajganj district through the Socio-Economic Index (SEI).

Data Sources and Methodology

The current study is based on quantitative data analysis, and data are collected from primary as well as secondary data sources. This study used questionnaires, interview schedules, focused group discussions, and observation methods in primary sources, whereas in secondary sources, it considered data and documents related to village officials. This study analyzed 100 respondents and selected purposively 20 respondents from each Vantangiya village, Baluahiya, Hathiyhwa, Nursery 24, Nursery 27 and Nursery 28. After collecting the data, the socio-economic status of the Vantangiya community of Vantangiya villages in Mithaura block of Maharajganj district analyzed through the socio-economic index. For this, the current study used the method to calculate the socio-economic index as follows:

Socio-economic Index = {1/2 Social Index} + {1/2 Economic Index}



Vantangiya Villeges in Mathura Block, Maharajganj District

Fig. 1

Socie-Economic Index– The social index is measured by many indicators like health, demographic, and educational factors that impact a person's family or social position. The sum of the health, demographic, and educational indices is thus the social index.

Social Index = (1/3 Health Index) + (1/3 Demographic Index) + (1/3 Educational Index)

Health Index: Health is a major component of social index which affects society directly or indirectly. In this paper access of health and maternal facilities, standard toilet facilities, availability of safe drinking water and electric facilities are included as health indicators (**Table-**1).

Health Index = Actual Value – Minimum value/ Maximum Value – Minimum Value

Table-1: Health-related Variables and Value

Variables	Values
Access Health/ Maternal Care	No = 1, Yes = 2
Standard Toilet Facilities	No Facility/field = 1
Public Toilet = 2	
Pit/ Flush Toilet = 3	
Safe Drinking Water	No Facilitity = 1
Surface Water = 2	
Tube well/ Handpump = 3	
Basic Electric Facility	No = 1, Have = 2

Source: Computed by Authors

Demographic Index: Demography directly affects development of any society. People's marital status and family size are playing a key role to decide their level of socio-economic development (**Table-**2).

Demographic Index = Actual Value–Minimum value/Maximum Value–Minimum Value

Table-2: Demographic Variables and Code

Variables	Values
Age of Marriage	Less than 21(Male) 18 (Female) = 1, 21-25 (Male) 18-21 (Female) =2, Above 25(Male) 21 (Female) = 3
Size of Family	Above 5 members = 1 5 members = 2 4 members = 3 3 members = 4 Less than 3 members = 5

Source: Computed by Authors

Individual Educational Index = Actual Value/ Maximum Value

Education occupies a prominent role in the social index. An educated society achieves new dimensions of socio-economic development (**Table-**3).

Table-3: Educational Category and Code

Category	Code/Values
No Education/ Illiterate	1
Primary Incomplete/ Literate	3
Primary Complete	5
Junior High School	8
High School	10
Secondary	12
Graduation	15
Post Graduation	17
Ph.D/Other Advanced Study	18

Source: Computed by Authors

Economic Index: The aspects that affect a person's or family's financial situation, such as income, spending, involvement in community events, occupation, and land ownership, have an impact on the economic index (**Table-**4). With the use of the Socio-Economic Index (SEI) measuring formula, the following tables are constructed for the SEI of respondents of the different villages of Vantangiya community in Mithaura Block of Maharajganj district (**Table-**4 and 5).

Economic Index = Actual Value–Minimum Value/ Maximum Value–Minimum Value

Table-4: Economic Variables with their Category and Value Category

Variables	Values
Monthly Income (Expected)	Up to 10000=1
10000-20000 = 2	
Above 20000 = 3	
Expenditure Less than Income	Yes =2, No =1
Participation in Community Events	Yes =2, No =1
Occupation	No Job = 1
Day Labour/ Farmer/Housewife = 2	
Government/ Private Job = 3	
Land Ownership	
(Household)	Up to 1 Bigha = 1
1-3 Bigha = 2	
Above 3 Bigha = 3

Determining Standard Value for Socio-Economic Index

For analysis and comparison, there is a need for a standard value of the Socio-Economic Index (SEI). To do so, I have assumed a standard value for each variable. For example, the values for the "Age of Marriage" variable are 1,2 and 3 representing ages below 21(male) & 18(female), age between 21-25(male) and 18-21(female), and age above 25(male) & 21(female) respectively. Here the standard value for this variable is 2 or the age of marriage between 21-25(male) & 18-21(female). The list of variables and their standard value (**Table-**10) are tabulated below:

Table-10: Variables and Their Standard Value

Variables	Values	Standard Values
Access Health Care/Maternal Care	No = 1, Yes = 2	Yes = 2
Standard Toilet Facilities	No facility/field = 1 Public Toilet = 2 Pit/flush Toilet = 3	Pit/flush Toilet =3

Contd...

Safe Drinking Water	No facilities = 1 Surface water = 2 Tube well/Handpump = 3	Tube well/ Handpump = 3
Basic Electric Facilities	No=1, Yes=2	2
Age of Marriage	Less than 21 years(male) & 18 years(female) = 1 21-25 years(male) & 18-21 years(female) = 2 Above 25 years(male) & 21 years(female) = 3	21-25 years(male) & 18-21 years(female) = 2
Size of Family	Above 5 members = 1 5 members = 2 4 members = 3 3 members = 4 Less than 3 members = 5	4 Members = 3
No Education/Illiterate	1	Secondary = 12
Primary Incomplete /Literate	3	
Primary Complete	5	
Junior High School	8	
High School	10	
Secondary	12	
Graduation	15	
Post Graduation	17	
PhD/Other Advanced studies	18	
Monthly Income (Expected)	Up to 10000=1 10000-20000=2 Above 20000=3	10000-20000 = 2
Expenditure less than income	No =1, Yes = 2	Yes = 2
Participation in Community Events	No =1, Yes = 2	Yes = 2

Contd...

Occupation	No Job = 1 Day Labour/Farmer /Housewife = 2 Government/Private Job=3	Day Labour/ Farmer /Housewife = 2
Land Ownership (Household)	Up to 1 Bigha=1 1-3 Bigha=2 Above 3 Bigha=3	1-3 Bigha = 2

Source: Computed by Authors

By putting the standard values in the Socio-Economic Index (SEI) measuring formula,

I get the standard value for Socio-Economic index (SEI) = ½ (Social Index + Economic Index) = ½ (0.722 + 0.625)

Socio-Economic Index (SEI) = ½ (Social Index + Economic Index)

Standard Value for SEI = 0.674

Determining Mean Value for Socio-Economic Index (SEI) for different Vantangiya Villages of Mithaura block.

With the help of statistical techniques:

(1) Mean value of SEI for Baluahiya village = 0.414
(2) Mean value of SEI for Hathiahwa village = 0.455
(3) Mean value of SEI for 24-Nursery villages = 0.383
(4) Mean value of SEI for 27-Nursery villages = 0.511
(5) Mean value of SEI for 28-Nursery villages = 0.533
(6) Mean value of SEI for all these 5 villages = 0.459

Socio-economic Status of the Baluahiya Villages

The socio-economic status of the Baluahiya village covering the social and economic indicators is not better at all as none (0%) of the respondents reported standard socio-economic status. The mean SEI value for respondents of the Vantangiya community in Mithaura block is 0.459 and only 35% of respondents of this village whose SEI are 0.459 or above. It can easily be predicted that the

maximum of the respondents of the vantangiya community in Baluahiya village are not have better socio-economic status. The basic social and economic facilities and infrastructure are not available in this village.

Socio-economic status of the Hathiahwa Villages

The socio-economic status of the Hathiahwa village covering the social and economic indicators is not good as only 5% of the respondents have standard socio-economic status. The mean SEI value for respondents of the Vantangiya community in Mithaura block is 0.459 and 50% of respondents whose SEI are 0.459 or above. So the socio-economic status of the Hathiahwa village is not as good as required and the basic social and economic facilities and infrastructure are not available.

Socio-economic status of the 24-Nursery Villages

The socio-economic status of the 24-Nursery village covering the social and economic indicators is not good as only 5% of the respondents have standard socio-economic status. The mean SEI value for respondents of the Vantangiya community in Mithaura block is 0.459 and only 15% of respondents whose SEI are 0.459 or above. So the socio-economic status of the 24-Nursery village is not good and the difference between the mean SEI of this village and the individual SEI of the respondents shows the inequality in their socio-economic status.

Socio-economic status of the 27-Nursey Villages

The socio-economic status of the 27-Nursery village covering the social and economic indicators is good as 15% of the respondents have standard socio-economic status. The mean SEI value for respondents of the Vantangiya community in Mithaura block is 0.459 and 50% of respondents whose SEI are 0.459 or above. So the socio-economic status of the 27-Nursery village is comparatively good among vantangiya villages.

Socio-economic status of the 28-Nursery Villages

The socio-economic status of the 28-Nursery village covering the social and economic indicators is good as 10% of the respondents have standard socio-economic status. The mean SEI value for respondents of the Vantangiya community in Mithaura block is 0.459 and 55% of respondents whose SEI are 0.459 or above. So the socio-economic status of the 28-Nursery village is comparatively better among vantangiya villages. The homogeneity in the mean SEI of this village and the individual SEI of the respondents shows equality in their socio-economic status.

Comparison of socio-economic status among Vantangiya villages of Mithaura block

The mean SEI value is 0.459 for the 100 respondents from different villages of the Vantangiya community in the Mithaura block of Maharajganj district. The mean SEI value for respondents of Baluahiya (0.414), Hathiahwa (0.455), 24-Nursery (0.383), 27-Nursery (0.511), and 28-Nursery (0.533) villages is different and this difference in the SEI level indicates that 27-Nursery and 28-Nursery are maintaining better socio-economic status than the other three Vantangiya villages. Comparing with the standard value of SEI (0.674), none of the respondents in the Baluahiya village have standard socio-economic status; only 5% of the respondents in the Hathiahwa and 24-Nursery village have standard socio-economic status; and 15% and 10% of the 27-Nursery and 28-Nursery, respectively.

Conclusion

This comprehensive and comparative study discussed the socio-economic status of the five Vantangiya villages in the Mithaura block of Maharajganj district. A multidimensional socio-economic index is used to measure the socio-economic status of the Vantangiya community. The Socio-Economic index is the aggregate result of the social index and the economic index. The social index is also subdivided into the Health Index, Demographic Index and Educational Index. The study analyzed 100 respondents from different villages of the Vantangiya community and indicates that 27-Nursery and 28-Nursery villages are in better socio-economic condition than the other three. This study also indicates that there is a huge need for basic socio-economic and infrastructural facilities in these Vantangiya villages to uplift the socio-economic status of the people of the Vantangiya community.

ASSESSMENT OF WILDLIFE HABITAT MANAGEMENT IN MUKUNDRA HILLS TIGER RESERVE, RAJASTHAN

Ms. Aayushi Jain and Dr. Ajay Vikram Singh Chandela

Abstract

Many researches have been done from time to time at local and global level in the context of climate change and biodiversity loss, many reports have been published. However, we all can feel these changes around us. We see the increasing environmental pollution around us and its impact on the life on land. This crisis has increased further due to changes in land use pattern in the last few years. With time, the area under forest cover and water bodies is decreasing while the area under man-made landscape is increasing. This destruction of natural habitat has led to greater decline in biodiversity. The 2022 global Living Planet Index shows an average 69% decrease in relative abundance of monitored wildlife populations between 1970 and 2018. Therefore, keeping in mind the need to conserve biodiversity, we should pay attention to the conservation of their natural habitats and saving top predators is essential for natural habitat conservation. Top predators, like tigers play an important role in maintaining the harmony of the planet's ecosystems. By preying on herbivores, tigers help to keep the balance between the prey animals and the forest vegetation which they feed upon. From the world's largest mangrove forests in the Sundarbans, to the snowy mountains in Northeast China and Russia, protecting wild tigers and their natural homes provides benefits for thousands of species and millions of people. (Why Tigers, n.d.) So we need to study their natural habitats, issues and solutions. This paper is based on common issues found in reserved forest areas. For example, it has been almost ten years since Mukundara Hills Tiger Reserve was declared a tiger reserve, but even today human settlements are present here. However, during the survey it was revealed that the residents themselves are not safe here. They also want to go out of these difficult situations and live a safe and healthy life. Apart from this, the context of water, food and safe habitat for wildlife has been discussed in this research paper also. Satellite images and field survey have been used for analysis. This forest area was also inhabited by

wild animals earlier and even at present there has been no significant change in this area. Most of the human settlements here are natural. Only a few road routes have been constructed. These can also be replaced by the Delhi-Mumbai Expressway in the future and made wildlife-friendly. Therefore, this area can be made a safe wildlife habitat. Moreover, the connectivity of Mukundra Hills Tiger Reserve with Bhainsroadgarh Wildlife Sanctuary in the south and Ramgarh Vishdhari Tiger Reserve and Ranthambore Tiger Reserve in the north makes it an excellent habitat for wildlife.

Introduction

In the Era of Machines and Development, many efforts are being made for environmental protection by the United Nations at the global level for the conservation of biodiversity. In this series, in the Conference on Sustainable Development held at Rio de Janerio in the year 2012, SDG goals were proposed by the United Nations. The purpose of which was to present goals globally to deal with the environmental, political and economic challenges faced by all countries of the world. In this series, in September 2015, United Nations Summit on Sustainable Development was organized in New York and the General Assembly adopted the 2030 Agenda for Sustainable Development with 17 SDGs. This research paper is based on one of them, on SDG 15: 'Life on land.' This goal includes study of our planet's ecosystem. As we know, without forest, there is no possibility of sustainable life on earth, but for the protection of forests, the presence of wildlife is also essential. Conservation of both forests and wildlife is essential for a balanced and secure life on earth, as stated as "The real wealth of the nation lies in the resources of the earth – soil, water, forests, minerals, and wildlife (Racgel Carson) If seen in the context of Rajasthan, the number of wild animals like bear, panther and tigers is increasing continuously, and for their protection it is necessary to study the available forest areas, which provide suitable living conditions for the wildlife. Moreover, seeking a favourable habitat for the cheetahs brought to the Kuno National Park in Madhya Pradesh, is also a need of the hour. To fulfill this objective, we need a place which has been preserving wildlife even in ancient times and which has not changed much even today, like Mukundra Hills Tiger Reserve. Although there are some challenges in front of Mukundra Hills Tiger Reserve even today, but their solution can be derived. In this research paper, we will discuss about those challenges and their solutions.

Study Region

Study area of this research work is Mukundra Hills Tiger Reserve, which has considerable diversity in topography, climate, vegetation, water resources etc. It is situated in the extension of Hadoti Plateau and Aravalli in the south-eastern Rajasthan, where Chambal, Bamani, Ahu, Kalisindh etc. rivers give life to land, make the forest flourish and create fertile plains.

Mukundra Hills Tiger Reserve (MHTR) was formed in 2013, which includes the area of Mukundra Hills National Park, Dara Sanctuary, Jawahar Sagar Sanctuary and National Chambal Gharial Sanctuary (from Garadia Mahadev to Jawahar Sagar Dam), which constitutes the core area of the Mukundra Hills Tiger Reserve in the Rajasthan. The tiger reserve is spread over an area of 759.99 square kilometers and is located in Ladpura, Sangod, Ramganjmandi tehsil of Kota district, Jhalarapatan tehsil of Jhalawar district, Talera tehsil of Bundi district and Rawatbhata tehsil of Chittorgarh district in Rajasthan. Jawahar Sagar Sanctuary is located between North Latitude 24°56' to 25°7.5' and East Longitude 75°26.50' to 75°41'. It is located 35 kilometers from Rawatbhata and 75 kilometers from Bundi. It is governed by the Government of Rajasthan Notification No. F 3(5) (13) Rev. 18/73 dated October 9, 1975 was declared as a sanctuary. The Mukundra Hills Tiger Reserve is named after the narrow central range with two continuous flat-topped and almost parallel hills, which is part of the Vindhya Range system, which extends from the Chambal River to Kalisindh and is about 80 kilometers in length and is 2 to 5 kilometers in width.

Objectives

(1) To analyze the problems faced in harmonizing the habitats of all living beings on the Earth as SDG 15.

(2) To study Mukundra Hills Tiger Reserve as suitable wildlife habitat for ever increasing tiger population in Rajasthan.

(3) To evaluate significance of Project Tiger in Rajasthan.

Database and Methodology

This research work is based on both primary and secondary data. The suitability of vegetation, water and habitat in the forest area has been studied with the help of satellite images and for its authentication, the area was surveyed. Satellite images of LANDSAT 8 have been used to analyze the forest area and health of vegetation. NDVI is calculated using Raster Calculator tool. In addition to this field survey was

done through schedule to study the human impact and environmental condition of villages located in Mukundra Hills Tiger Reserve. During this survey, information was obtained from the residents about their lifestyle and their dependence on the forest. Apart from this, their impact on the forest was also analyzed. Some research papers and books related to forest management and biodiversity have been studied. Newspapers have been mainly used as secondary data to get information about positive and negative changes happening in Mukundra Hills Tiger Reserve from time to time. Maps were prepared with the help of open-source software. To create maps of the study area, shapefiles taken from forest department portal- 'rajforest' and 'Survey of India' portal were used.

Factors affecting wildlife habitat in Mukundra Hills Tiger Reserve

Water Resources

Mukundra Hills Tiger Reserve is located in the region of Rajasthan with more than 70 cm of rainfall. The only perennial river of Rajasthan, Chambal, and its tributaries, passes through the Mukundra Hills Tiger Reserve. They provide water to the Mukundra Hills Tiger Reserve for most of the year. The topography of Mukundra Hills Tiger Reserve also ensures the availability of water here. The Vindhyan range extends up to the Mukundra Hills Tiger Reserve, locally called Mukundra Hills, from which the rainwater seeps down and accumulates throughout the year in the foothills and lower areas of the valleys. Apart from this, the Forest Department is also conserving more than 100 natural and artificial water bodies in this region. (**Fig.** 1)

Food and Habitat

70 percent area of Mukundra Hills Tiger Reserve is covered with mixed deciduous forest. Dhok (Button), Khair (Black kutch), Churail (Indian elm), Amaltas (Golden shower), Sal, Gurjan, Palash (Bastard), Arjun, Tendu, Ber, Behda (Beleric Myrobalan), Mahua (Buttercup), Khejdi, Babool, Neem, Banyan, Peepal, Khechda, Khakara, Bamboo, Bilvapatra, Amla and many other species of deciduous forests found here. It provides favorable habitat and sufficient food to the wildlife (**Fig.** 2). Thorny autumn forests are found here, whose dry leaves provide food for herbivore animals chinkara, chital, sambar, nilgai, deer, and langurs even in autumn, which provide ample prey base like wolf, jackal, fox, mongoose, wild cat, civet, porcupine, wild boar, panther and tigers. Thus, there is enough food even for carnivorous animals. From the point of view of natural habitat, the total area

Fig. 2

of Mukundra Hills Tiger Reserve is 759.99 square kilometers, out of which 417.17 square kilometers comes under the core area and the rest under the buffer area. Out of the core area, the area of 82 square kilometers is surrounded by wire fencing. The grassland is well developed within this wire fencing and sufficient prey base is also available in it. Apart from this, one enclosure of one hectare has been made in Selzar area of the tiger reserve and another enclosure of 28 hectares has been made in Sawan Bhado area. (Source: Dainik Bhaskar Newspaper, 05.05.2023) In addition to the above, Mukundra Hills Tiger Reserve has a glorious history as an abode of tigers, but now due to changing land use pattern some disparities have arisen in this area which need to be resolved.

Roads and Railways

National Highway 52 and Delhi-Mumbai railway line pass through Mukundra Hills Tiger Reserve for length of about 50 kilometers. The high speed of vehicles and blind turns of the roads have many times led to the death of wildlife. There are 30 villages located in the core and buffer area of Mukundra Hills Tiger Reserve, in which more than 1500 families reside. Although about 200 families have been relocated from here in the last 8 years, but still the residence and farms of the rest of the families are existing in the forest area. These forest dwellers go to the nearest cities only through the forest area to get the goods they need and for employment. It is dangerous for the life of both humans and wilds (**Fig.** 3).

Project Tiger in Rajasthan

The Tiger Project in Rajasthan started in 1973 when Ranthambore was declared as the first Tiger Reserve of Rajasthan in 1973-1974. In the next phase of the Tiger Project, Sariska was declared a Tiger Reserve in the year 1978-79. But even after three decades of the Tiger Project, there was a continuous decline in the number of tigers in Rajasthan. Tigers vanished from Sariska Tiger Reserve in the year 2005 and only 14 tigers were left in Ranthambore Tiger Reserve. But gradually the conditions started improving; the number of tiger reserves was increased, villages were relocated from Ranthambore and Sariska, mining and deforestation were banned and as a result, gradually the number of tigers started increasing in Rajasthan, which can be understood from the following table: At present, there are about 115 tigers present in Rajasthan. With the formation of Mukundra and Ramgarh Vishdhari Tiger Reserves, a natural wildlife corridor has been created for tigers in the south eastern part of Rajasthan. The number of tigers has grown

substantially in Rajasthan. Due to increasing population of Tigers, the tigers have started migrating to nearby forests of Madhya Pradesh and Rajasthan. This depicts the picture of success of the Tiger Project in Rajasthan.

Conclusions

In conclusion we can say that, Mukundra Hills Tiger Reserve has favourable natural conditions for the habitat of wildlife, but due to anthropogenic activities some anomalous conditions have arisen here. For example, on July 15, 2013, a tiger 'Broken Tail' had come from Ranthambore Tiger Reserve towards the Darrah forest area while roaming. But unfortunately, he was crushed to death by the Rajdhani Express on the Delhi-Mumbai rail route. After this, about 6 years later, in the year 2019, the T-98 tiger, leaving Ranthambhore Tiger Reserve and traveling about 150 kilometers, reached the Darrah region of Mukundra Hills Tiger Reserve via Kalisindh river.

This is the second case of moving from one tiger reserve to another through forest area. Therefore, there is a need to improve following conditions as much as possible and make them wildlife friendly. As (1) The villages should be relocated soon (2) The speed of vehicles should be regulated (3) Grasslands should be developed (4) There is uncertainty of rainfall in Rajasthan. Therefore, to deal with such situations, artificial water points should be developed and water availability should be ensured throughout the year using solar pumps as proposed in Ramgarh Vishdhari Tiger Reserve (5) Security walls should be built around the forest area so that wildlife stays away from rail and road routes and human settlements (6) Tiger reserves of south-eastern Rajasthan should be connected with each other by developing wildlife corridors. Although after the declaration of Mukundra Hills Tiger Reserve as such, many efforts are being made by forest department, and central and state government for the development of Mukundra Hills Tiger Reserve. In view of the protection of wildlife, mining work and deforestation has been banned in this area. Grasslands are being developed so that sufficient food is available for herbivorous animals and sufficient prey base can flourish in the forest. Now if there is any threat to wildlife it is from road and rail routes and human settlements. Forest Department. Apart from this, to ensure wildlife conservation in the area, measures have been taken in the Bharatmala Project, under which Delhi-Mumbai Expressway is being constructed. For wildlife conservation an eight-lane soundproof twin tunnel is being constructed. Along with this, the relocation of six villages settled in core area has also been done. (Shah, 2020)

IMPACT OF ROADSIDE FRICTION ON ROAD CAPACITY IN ALIGARH CITY, INDIA

Dr. Fatma Mehar Sultana, Rehma Nooreain and Dr. Naushaba Naseem Ahmed

Abstract

Indian cities are notorious for poor road capacity and the slow average mobility. Aligarh city has massive problem of traffic congestion and inadequate transportation infrastructure as the narrow lanes and roads crisscross the city. Absence of the well-designed junctions, footpaths and cycle tracks makes it difficult for pedestrians, cyclists and vehicles to commute safely. Moreover, the lack of traffic management has led to the usual traffic congestion and frequent road accidents. Inadequate parking space causes traffic jams due to road side unauthorized parking. One of the important reasons for this traffic chaos is that the city has one of the fastest growing populations due to the migration of people from rural areas as well as from other parts of the state and country, mainly for education and employment. It is the 77th most populous city in India. Due to Covid -19 lockdown restrictions much of the ridership in Aligarh city was curbed. Still, not much change was being observed in the side friction and traffic congestion. The busy roads of Aligarh city have emerged as the site of parallel economic structure for the migrants, poor and the marginalized section of the city. In this paper we have done a comparative study of two roads of the busy market areas of the Civil Lines zone of Aligarh city during the Lockdown, following all the protocols. The purpose of the study is to analyze the degree of influence the road side friction has upon the road capacity caused by the road side economy. The paper concludes that the side friction has considerable negative impact on the capacity of roads in Aligarh's market areas.

Introduction

Road transportation system has been playing a vital role in the socio-economic development of cities all over the world. Road traffic in India is marred by poor condition and below par performance. The main focus in the studies regarding speed-flow relationship of road traffic is on geometry, street type and urban environment

of roads. Recently many studies have concluded that in the cities of the developing world there are some activities going on or along the roadsides which influence the capacity of the road network which is known as the side friction (R. Amudapuram et.al, 2016). Road capacity is defined as the maximum sustainable flow rate at which vehicles can be expected to traverse a point or uniform section of a lane or roadway during a given time period under the prevailing roadway traffic and control conditions (IRC, 1990). The condition is getting worse in the cities of developing world where the increasing transport demand is causing the deterioration in the road capacity of the arterial and the local roads, and the inefficient performance of the traffic system (Salini.S et. al., 2014). As per the Indian scenario, the presence of the roadside markets and vendors is a common observation in every city. They attract people to stop by, which reduces the effective road width due to the roadside parking of the vehicles and other parking and un-parking maneuver. Due to lack of the meaningful employment for migrants and unskilled and semiskilled individuals, and the unavailability of the specified area for their informal fringe economic activities; vendors, rag pickers, mechanics etc. are also found to work along the roadside. The presence of road side markets, vendors, food stalls and the lack of pedestrian facilities compel people to walk on or along the road which disturbs the traffic flow. In consequence, traffic flow is considerably interrupted. It diminishes the performance of traffic operations and undermines the capacity and the functional integrity of the road. The road side frictions have negative effect on the road capacity as the width of road decreases and it becomes narrow. Side friction leads to decrease in the speed of vehicles, aids in the delays and becomes a cause of accidents. Literature review reveals that very little work has been done in 'Y' category cities in India like Aligarh till date to measure the impact of roadside friction upon the capacity of urban roads. This study intends to measure the influence of roadside frictions on the capacity of road in Aligarh city during the lockdown period in order to establish that even the regulated opening of the city creates unmanageable side friction reducing the capacity of roads below the base value. The study will be a precursor to the road traffic administration of Aligarh Smart city to find out the ways to regulate the unmanageable urbanization and the exponential motorization.

Study Region

Aligarh has been classified as class Y city (HRA, 2015) and one of the National Priority Cities and potential urban growth centers of India (Report of National Commission on Urbanization, GOI, 1988) located outside the National Capital

Region (in 150 km radius). It is the administrative headquarters of Aligarh district, and lies approximately 130 km south east of the capital, New Delhi. Aligarh Muslim University, the world famous seat of learning, is located here. Besides, it is a hub of a large number of small scales household and cottage industries, some of important large-scale food and agro-based industry, and the brass and lock industries. The decadal population growth rate of the city is 30.40 percent for 2001-11(**Table-**1).

Table-1: Geometric Parameters of the Roads under Study

Road Characteristics		Road	
		Marris Road	Dodhpur Road
Geometric condition	Road Types	Single Carriageway 2 Way	Single Carriageway 2 Way
	Carriageway Width	7 m	7.2 m
	Shoulder Width	2.7	1.1
	Road Alignment	Straight	Straight
	Footpath Width intermittent	2.6 m	2.5 m
	Road length	2.57 km	3.08 km
Environmental condition	Weather Condition	Day/Dry	Day/Dry
	Urban/Suburban	Urban	Urban
	Pavement Condition	Paved/Near to Smooth	Paved/Smooth
Traffic control condition	Nearby Major Intersections	Present	Present
	Traffic Signs	Present	Absent
	Pavement Markings	Present	Absent

Source: Based on Survey, 2021

The annual population growth of the city is reported as 3.16, 2.97, 2.89 and 2.81 percent for 4 consecutive years from 2017 to 2020 respectively. The estimated population of Aligarh city is 1,013,089 in 2021(UN- World Population / prospects). The population density of the city has increased from 14,500 persons per square km in 1971 to 24,573 persons per square km in 2011(excluding the University area). 10 percent of the urban population has spread beyond the city limits and in the towns which are also dependent on this city for their major needs.

The city is also having a high rate of motorization. The growth of road length network is not keeping pace with it.

Objectives

(1) To measure the vehicle composition and traffic flow rate of Marris and Dodhpur roads.

(2) To identify the major sources of side friction on these roads and to estimate the magnitude of side friction.

(3) To calculate the actual capacity of both roads.

(4) To estimate reduction in base capacity of both roads due to the side friction.

Database and Methodology

The present study is based on the primary sources of data generated through the comprehensive field survey, traffic counting (TC) survey, side friction (SF) survey, and geometric survey carried out during year 2021 in the month of April. The secondary data is collected from the Census of India (2011). For determining the influence of road side frictions on the capacity of road, two roads of Aligarh city are selected, with roadside friction activities. These are the Marris road and the Dodhpur Road which are undivided two lane two ways (2/2 UD). The survey was conducted for four hours from 8:00 am to 12:00 pm on these two roads. On each road a 50-meter length is specified for the surveys. In this study the evaluation of traffic flow, roadside friction (Pal and Roy, 2016) and capacity (Indonesian Highway Capacity Manual Urban Roads, 1993) is done according to the techniques mentioned in the sources shown in the parentheses. The traffic count survey was done manually by counting the number of each type of vehicle that had passed the fixed spot on the road in both the directions for every 5 minutes under four categories namely, two wheelers, animal drawn vehicles, three wheelers, cars and heavy vehicles. The vehicles in these categories are heterogeneous in nature. Therefore, for finding the total flow each vehicle type is converted into the homogenous category. Flow is calculated by converting the volume of vehicles per 5 minutes into the equivalent PCU (passenger car unit) as per IRC code. The peak hour factor (PHF) is calculated for finding the peak flow of an hour by the formula given by (HCM, 1965) as:

$$PHF = v \frac{60}{av} \Big/ 12xv \frac{5}{av}$$

Average volume during the peak 60 minute period v_av^60 is divided by twelve times to get the average volume during the peak 5 minute's period v_av^5. For the side friction survey a section of 50-meter length on both roads was delineated and width was measured with the help of a measuring tape. On these two sections of the both roads the survey was done to count the number of pedestrian /hour walking, vehicles parked or stopped on their way for a while /hour/width, number of vendors standing/hour/width, number of stray animals moving/hour/width, number of beggars present along the road/hour/width. Pedestrian is considered unit of friction. Impact of side friction included the physical dimension of the side friction as well its position on the carriage way. Area effect of an element of friction is considered as the ratio of projected area of a particular friction to pedestrian and expressed as area ratio (AR). Positional disturbance effect of an element is calculated as the ratio of distance of particular midpoint of strip from edge of carriageway on which friction element is positioned to midpoint of the edge strip named as distance ratio (DR). Weight factor for each element is determined by summing up area ratio and distance ratio. After assigning weight these frequencies are converted into a single unit of roadside friction index (RSVI). To plot the side friction frequency graph all categories of side friction frequencies are summed up and then average frequency per five minutes is calculated for the whole study duration. The geometric survey was done to measure the width of the carriageway, and its edge strips and the middle strip. These capacity parameters have helped in finding the capacity of two roads. Capacity is F calculated as follows.

$$C = C_0 \times FW \times FKS \times FSD \times FSF \times FCS$$

Whereas:

C_0 = Base Capacity

SF = Curb and shoulder adjustment factor

FW = Carriageway width adjustment factor

FSF= Curb and shoulder adjustment factor

FKS = A directional split adjustment factor

FCS = Side friction adjustment factor

FSD = City size adjustment factor

The actual capacity is determined by multiplying the base capacity with all the adjustment factors as mentioned above. The capacity is dependent upon the

geometry of road (the width of road, shoulder width, city size, and median width), side friction activities and the city size. So the values of different adjustment factors have been taken from (Indonesian Highway Capacity Manual Urban Road, 1993). Actual capacity of both roads is estimated by calculating percentage of base capacity reduction.

Results and Discussion

Composition of Vehicles of Roads, (2021)

Traffic Composition is shown in Fig 2 and it is clearly indicated, at Marris Road the vehicle composition is found to be as; two wheelers' 61 percent (bicycle 2.99%, motorcycle and scooter 58.543%), animal drawn vehicle 0.5 percent, car 20 percent, e-rickshaw 15 percent, bus 2 percent and others 2.07 percent. On Marris Road two wheelers and cars have the greatest contribution in traffic flow. However, at Dodhpur it is found that two wheelers constituted 62 percent (bicycle 3.08%, motorcycle and scooters 59.35%), car 14.24 percent, e-rickshaw 18.08 percent and others 5 percent (animal drawn vehicles, truck, van, tractor etc.) of the total traffic. Two wheelers and e rickshaws are the most ubiquitous vehicles here. (Fig 1)

Traffic Flow Analysis

The traffic flow is greater at Marris Road as compared to at Dodhpur road. At Marris Road peak hour volume is 2269.353 pcu/hour observed in between 9.40am-10.40am. Marris road's connectivity with the Center Point, a major marketing area of Aligarh city, Ramghat road and railway junction is the main cause of greater traffic flow. At Dodhpur road peak hour volume is found to be 1803.6 pcu/hour between 9.20 am-10.20 am and it is mainly due to the vendors and regular shops attracting the major share of the traffic flow.

Composition of Road Side Friction

Fig 2 and 3 show, at Marris Road main components of the roadside friction are roadside parking, vendors, food stalls, squatters etc. occupying the footpath and allowing less space for pedestrian's movement resulted into the movement of pedestrians on the road or along the road causing hindrance to the flow. There are three schools located along this road but because of COVID 19 their contribution in hindering the flow is negligible due to the online. In normal time these schools cause considerable road side frictions.

Fig. 1

At Dodhpur road the roadside friction is mainly due to the presence of vendors compelling pedestrian movement along the road. The roadside parking has emerged as the second biggest factor causing the side friction on Dodhpur road as here no official legalized parking space is found. Squatter, begging and dumping also act as other sources of friction for the traffic flow on this road. Due to increasing rate of in migration and lack of suitable employment more people are turning up to the road side informal economy as vendors. Due to absence of the decent public transportation and traffic infrastructure, private ownership of vehicle is increasing but absence of proper parking facilities it is creating more road side frictions. Road side friction is greater at Dodhpur road as compared to at Marris Road. At Dodhpur road the peak hour for the roadside friction is between 9.45 am to 10.45 am. The frequency of roadside friction count is found as 110-116 per hour. Roadside vendors, Restaurants, and Market attracted the flow during this time. At Marris Road the frequency of roadside friction is found to increase and decrease alternately and being maximum between 10.35 am-11.35 am.

The frequency of friction is found to be 80-75 per hour as it is the time when restaurants, shops, banks, offices etc. located here and the vendors attract the flow causing road side parking and pedestrians' movement on the road. It is evident that the overall roadside friction during peak hour is less at Marris Road as compared to Dodhpur road. During the study it was found that the edge of the roads experienced more side friction as compared to the middle part of the road. Therefore, for the better results the sections of both roads under the study were divided into two portions, one meter edge strips on both sides of the carriage way and the remaining 5 meter and 5.2-meter middle strip for Marris and Dodhpur road respectively. **Table-**2, 3 and 4 shows a detailed analysis of the weighted factors assigned to the different types of side friction element found along the edge strips and the middle strips of Marris Road and Dodhpur road. di is distance of ith friction element from carriageway edge, A_i projected area of ith friction element, AR is area ratio, DR is distance ratio and PA is projected area. These calculated values are used to develop the road side friction index (RSFI) (**Fig.** 2 and 3). It is clearly indicated in **Table-**3 that RSFI is greater at Dodhpur road (3937) as compared to that of Marris Road (2564.4). Therefore, we can deduce that the encroachment of road by the road side friction activities is greater at Dodhpur road as compared to that of Marris Road.

Capacity Analysis

Adjustment Factors of Parameters of Capacity is given by (IHCM1993) and Actual Calculated capacity of Marris and Dodhpur Road (2021). It is clearly revealed that the actual capacity of Marris Road being 2680.05 pcu/ hour is greater than the actual capacity of Dodhpur road which is 2297.47pcu/hour. The base capacity at Marris Road is decreased from 2900pcu/hour to 2680.05 pcu/ hour and at Dodhpur road from 2900pcu/hour to 2297.24 pcu/hour due to high and very high levels of side friction respectively. **Table-**5 shows the reduction in capacity of both roads due to side friction. This finding is in conformity to other studies conducted in India and Indonesia (Sulistyono et.al. 2018). These studies highlight a reduction of capacity to the extent of 10-60 % due to different elements of side friction (**Table-**5).

Table-5: Capacity Reduction in Study Region

Location	RSFI	Base Capacity	Actual Capacity	% Reduction in Capacity due to side friction	% Reduction in Capacity including side curb
Marris Road	3679.2	2900	2680.05	10.76%	19.63%
Dodhpur Road	4960	2900	2297.47	20.78%	20.78%

Source: Based on Survey, 2021

Conclusion

The study reveals that the private vehicles have greater contribution in traffic flow (80%) on both the roads as compared to the public transport. The activities which cause main roadside friction (94%) at Marris Road is mainly by the roadside parking and the pedestrian movement making. The activities along Dodhpur road are mainly pedestrian movement roadside parking and vendors, comprising overall 99 percent of the total side friction activities. RSFI calculated to show the magnitude of roadside friction is found to be greater at Dodhpur road (4960) as compare to at Marris road (3679.2). The percentage reduction of the base capacity only due to side friction is greater at Dodhpur road as compared to at Marris Road, thus, it concludes that the roadside frictions have a greater impact on the capacity of road. The availability of the legalized parking area on both the roads, specified area for the hawkers and vendors, and footpath for pedestrian movement can drastically reduce the frequency of roadside friction. Installation of the intelligent traffic monitoring system, regulation on loading and unloading of the passengers by e-rickshaws, redesigning and readjustment of roads, construction of a roundabout at Dodhpur intersection are some of the actions which are required to be implemented on the priority basis.

SPATIO-TEMPORAL DYNAMICS OF FLOOD SEVERITY USING MULTI-TEMPORAL SATELLITE DATA: A CASE STUDY OF KOSI FLOODS

Dr. Supriya and Dr. Shipra Soni

Abstract

Flood is a natural phenomenon and frequent disaster that occurs in the North Bihar Plain and causes damage to life and property almost every year. The main cause of floods in Bihar is usually known by people to be the shifting and slitting of rivers. The continuous silting has made the rivers shallow and losing their depth, so they are unable to face the forceful rain during the monsoons, which in turn results in breaking their banks and spreading water on the plains. Which is further reflected in the distinctive events like river course change and river capture in the flood plains of Bihar. Since floods increase each year, resulting in loss of life, property, and farm output, it is possible to use a generic approach as an estimate of flood damage. To mitigate flooding, spatial analysis is of paramount importance for the timescale and temporal characteristics of flood-affected areas. The Kosi River is one of the highly vulnerable to flood and is known for its frequent flooding, river course changes, and river-capturing events. The Kosi region faced a devastating flood on August 18, 2008, due to a breech at Kusaha village, which caused not even loss of property and lives but the change in the river course itself. Satellite imagining technology emerged as a powerful tool for the analysis of inundation areas and flood severity in the Kosi flood-prone basin during breech and flood. In order to better understand seasonal and yearly variations in the number of floods and to facilitate emergency response, this research provides an algorithm for mapping precipitation and flood inundation. Hence, the present study made an attempt to analyze the changes in rainfall and severity of flood using multi-spectral-temporal satellite data of the Kosi River basin for the 2008 Flood, Pre-flood (2007) and post-flood (2009) situations. The paper aims to describe thresholding and unsupervised classification methods to determine inundated areas, changes in persistent rainfall, and rising Kosi River water levels.

Introduction

Floods are the most widespread natural hazard that account for most damage and loss of life. They also can have serious secondary impacts on the economy and agriculture. Geographers have studied the complexity of such flood hazards for many years and have made significant contribution to their understanding. Flood is defined as any flow that exceeds the bank full capacity of a stream or channel and flows out of the floodplain, greater than bank full discharge. According to the World Meteorological Organization, a flood as a "(1) Rise, usually brief, in the water level in the stream to a peak from which the water recedes at a slower rate. (2) Relatively high flow as measured stage height or discharge. (3) Rising tide" (WMO, 1992). The magnitude of the floods and their probability of occurrence are strongly connected, although these relationships are regionally specific and depend on climatic conditions and characteristics of river catchment. On 18th August 2008, the eastern embankment of Kosi River was breached near Kusaha village, Nepal, about 12 km upstream of the barrage. At the time of breach, the river flow was below average, considering the same time-period in different years. The water inundated the adjoining villages of Kusha and Haripur (Nepal) immediately and reached Bhimnagar, Birpur (India) within a few hours. In Birpur, flood water rose alarmingly to a height of 5–6 ft within a short time after the breach. Subsequently, the flood water spread over a great extent covering Supaul, Saharsa, Madhepura, Araria and Purnea districts, causing severe damage to life and property.

In fact, after the 18th August breach, the Kosi River has altogether taken a new course, that of the 1930s, as reported by residents near Muraliganj. The Kosi River system is a monsoon-fed river system which has a long history of devastating floods in its lower catchment. After the 1954 floods in Nepal and Bihar, the flow of the Kosi River has been regulated by an embankment, constructed in 1963, on both sides of the river. The 2008 flood happened after breach of a levee on 18 August 2008 near Kusaha in Nepal, 12 km upstream on the eastern embankment of the river. The avulsion abandoned the current river course and the water followed an ancient channel midway through the alluvial fan. This led to inundation of a huge area, devastating the lives of millions of people (UNICEF Report 2008). Kosi River is considered as 'Sorrow of Bihar' since a long time due to its recurring and substantial flooding and repeated change in its course over the years. The change of river course has well documented in British rule. The river has changed its course in a westerly direction and it has laterally moved nearly 150 kilometers (Gole and Chitale, 1966; Wells and Dorr, 1987).

The movement of the river has not been gradual but of avulsive nature (sudden change in river course) originating from a nodal point (Wells and Dorr, 1987). The average avulsion frequency has been recorded as 24 years which is among the lowest in the world compared to 1400 years for the Mississippi river (Slingerland and Smith, 2004). Several paleochannels on the satellite image of the Kosi basin testify the migratory behavior of the river (**Fig. 1**). The river is typically braided in nature and has formed a very large alluvial fan due to a large sediment supply from the Himalaya and a generally aggregational regime. Further complications arise due to (a) very high rainfall in the catchment (1200- 2000 mm in most parts; Sinha and Friend, 1994), and (b) high seismicity in the hinterland causing landslides and large sediment production which eventually fill up the basin. The initial flood control schemes were introduced during late 19th century which included construction of marginal embankments, high dam at upstream section, river training in lower reaches and a series of barrages and canals. However, no consensus was reached and no definitive action could be taken until 1953. A very severe flood in 1953–54 and the subsequent social and political pressure led to the first serious attempts towards flood control the Kosi basin and the formulation of the 'Kosi project' in 1954. This project was primarily aimed at flood control and to provide irrigation for increasing agricultural productivity. The project started in 1959 and the river was diverted through the barrage in 1963. The embankments on both sides have been designed to protect nearly three thousand square kilometers of land in north Bihar and Nepal. Although the embankments have checked the lateral movements of the Kosi, the flooding problem continues in the Kosi basin and the objectives predicted in the Kosi project have been only partially met. Several large floods and frequent breaches in the embankments have continued to occur in the region. In addition, several adverse effects of the Kosi project have been noted viz. drainage congestion and water logging rise of river bed level, and reduction in crop productivity due to reduced silt flux on the floodplains (Ghani, 2001). In the view of above mention facts the present paper attempts to analyze the severity of 2008 Kosi flood and the spatio-temporal dynamics of flood severity of Kosi floods with pre (2007) and post (2009) flooding situation using multi temporal satellite data. It also examine the effectiveness of precipitation.

Study Region

The Himalayan terrain, the Kosi river is formed by the confluence of seven smaller streams, viz. Indravati, Sun Kosi, Tama Kosi, Likhu Kosi, Dudh Kosi, Arun Kosi and Tamar Kosi at different places in China, Tibet and Nepal,

before its entry into the Indian state of Bihar In India, the Kosi river merges with the mighty Ganges near Kursela village, Katihar District, Bihar. Kamla, Baghmati (Kareh) and Budhi Gandak are the major tributaries of Kosi in India, besides many minor tributaries like Bhutahi Balan. The mountain-fed Kosi River has a total basin area of nearly 84,739 sq.km of which only 11,842 sq.km lie within Indian Territory and spans a total length of 730 km from its source to the confluence with the Ganga at Baltara. (Gole and Chitale, 1966; Sinha and Friend, 1994). The Tibetan region of the Kosi basin comprises 22% of the total drainage area and is characterized by high elevation and flat plateau on the leeward side of the Himalaya with many glaciers and glacier lakes (Bajracharya et al., 2007). About 40% of the drainage area of the Kosi basin lies in the Nepal Himalaya and is characterized by alpine and mountainous areas.

The alluvial part of the Kosi basin in the Bihar plains in India comprises 38% of the total drainage area and comprises low elevation and flat plains with high population density (**Fig.** 1). The climate of this region is monsoon sub-tropical. The Kosi region or Kosi division is an administrative unit of Bihar comprising three districts i.e. Saharsa, Supaul and Madhepura. The present study is confined to assess the severity of deluge falling under this region. NASA's Shuttle Radar Topography Mission (SRTM) DEM (Digital Elevation Model) data shows that the topography of Kosi region ranges from 30 meters near the confluence in Ganga River to 89 meters near Kosi Barrage at Bihar – Nepal border.

Objectives

(1) To study interpolated precipitation map of three years i.e. 2007, 2008 and 2009 to understand the rainfall pattern of the study area.

(2) To assess side by side comparison of precipitation and flood intensity and to extract numerical values of the extent of flood in all three study years.

Database and Methodology

Climatic Research Unit (CRU) gridded Time Series data is used for preparing precipitation map. Flood inundation layer for each year was generated using ISRO's multi-temporal satellite datasets (2007 to 2009) comprising of either IRS WiFS (188 meters) / IRS P6 AWiFS (56 meters) / Radarsat ScanSAR Wide / Narrow (100 meters & 50 meters) acquired during the flood season of that particular calendar year are used. The Raster data of flood inundation was downloaded using compatible software and with the help of Kosi region vector data study area masked out.

The flood inundation layer for each year was delineated from satellite data by applying suitable classification technique. The precipitation map was prepared using the interpolation techniques in ArcMAP. Inverse Distance Weighted (IDW) was used to determine the temporal intensity of rainfall in Kosi region. Identification of flood prone area was done using the raster file in Global Mapper by using creating area feature using equal value tool in layer menu. The flood area vector layers were created and then smoothened using smoothing tool. The flood inundated area for each year was calculated and numerical values were noted in sq.km.

Results and Discussion

One of the main purposes of this study was to acquire interpolated precipitation map to understand spatio-temporal pattern of rainfall in Kosi region. The outcome of the rainfall pattern could be well understood (**Fig.** 1, 2 and 3 and **Table-**1, 2, 3 and 4.

The flood inundation map for all three years was prepared using ISRO's Bhuvan raster data. These raster data contained ISRO's multi satellite sensors ranging from IRS series (WiFS, P6 AWiFS) to microwave satellite data from Radarsat satellites (ScanSAR Wide/ Narrow). The water levels observed at different gauge stations were closely monitored during floods and attempts were made to program the satellite data during peak/near peak positions. The next step was to create flood inundation layer using image processing classification algorithms, water layer was extracted from the satellite data and integrated with the pre-flood river and water bodies layer to derive flood inundation layer. Finally annual flood layer was created. The flood inundation layers generated for different flood waves in a calendar year were integrated to generate the maximum flood inundation extent observed in that year (Fig 1, 2 and 3). The second objective of this paper was to show the flood intensity and extract numerical values to know the extent of flood in study years (2007, 2008 and 2009). This can be analyzed in data obtained through raster data processing obtained from ISRO (**Table-**2, 3 and 4) while the manifestation of deluge could be observed in above processed maps. The processed data of 2007, a year before the famous 2008 flood shows the maximum extent of inundated area of Kosi region was nearly 922 sq kms which was approximately 15.6 percent of the total area under Kosi region. In 2008, the inundated area nearly doubled and in about 1752 sq kms. It accounts around thirty percent of the total Kosi region area. Finally in 2009 which was the post flood year, there was a drastic fall in flood inundation in Kosi region. The flood inundated area reduced to barely 228 sq kms which was less than four percent of total area of the Kosi region. It is also a major fact that 2009 was an El Niño year and it had lesser annual precipitation in comparison of both 2007 and 2008 as well.

Conclusion

In this paper, we have determined the variation of intensity in rainfall with the help of CRU grided time series data, and the spatio-temporal variation is represented

in the rainfall map prepared through ArcMap IDW tools. The result clearly reveals that in 2008, the upper plain of the Kosi River received a higher amount of average mean rainfall (1800mm) than in the post- and pre-flooding years. It was caused by the breach in the upper Kosi basin of Bihar, which helped raise the water level in the entire area and cause flooding. The study also reveals the changes in flood-prone areas with the help of the extraction of flood-inundated areas in Kosi River for the same time period through the analysis of multi-satellite data acquired from different sensors ranging from IRS series (WiFS, P6 AWiFS) to microwave satellite data and Radarsat satellites (Scan SAR Wide/Narrow) data and further converted in pixels to area in Global Mapper by using the Create Area feature. It reveals that approximately 30 percent of the total area was inundated due to floods in 2008; therefore, only 15.52 percent of the area in 2007 and 3.84 percent of the area in 2009 were submerged. It has clearly represented through the flood severity maps that in 2008, the eastward part of the study area was highly inundated, which was changed after 2008 flooding through the westward due to the main channel shifting towards the west and creating a very high flood hazard risk zone. Hence, the combined use of multi-temporal imagery and metrological data analysis achieves the objective of preparing flood severity maps for the study area. The spatio-temporal precipitation data, flood data, and processed maps can be used for the purposes of identification of annual precipitation effectiveness and rainfall pattern in Kosi region threshold area, identification of constantly flooded areas, regulate land use in the inundated areas and spotting safer flood relief shelters. In order to raise awareness among researchers and the scientific community, the possible importance of this research is to include these efforts as part of general flood management measures that do not include structural measures aimed at reducing short-term and longer-term damage. It is also a simple and cost-effective methodology for flood management and mitigation.

GENDERED PERSPECTIVES OF MIGRATION TO GUJARAT: BEHIND THE NUMBERS

Dr. Harpreet Singh and Ms. Gauri Hanspal

Abstract

Migration is a complex phenomenon with profound implications for individuals and regions. This study explores migration to the state of Gujarat, India, shedding light on the gendered perspectives often overlooked in migration studies. Utilizing data from the Census of India 2011, the research analyzes the volume and patterns of in-migration, emphasizing the role of gender in shaping the demographic landscape of Gujarat. The introduction delineates the significance of migration, differentiating between internal and international migration based on administrative boundaries. It underscores the selectivity inherent in migration processes, driven by diverse factors such as age, marital status, education, gender, socio-economic status, and housing situation. Gujarat's status as a counter-magnet for individuals from economically constrained states is highlighted, with a focus on the megacity of Surat and other districts attracting migrants for varied opportunities. Maharashtra, Uttar Pradesh, and Rajasthan emerge as significant contributors to Gujarat's in-migrant population, playing pivotal roles in shaping migration dynamics. The study aims to uncover the nuanced narrative beneath migration statistics, emphasizing the often-overlooked role of gender. The spatial distribution of male and female in-migrants across different districts of Gujarat further reveals distinct patterns. Key findings highlight a notable gender imbalance in the in-migrant population, with higher female representation, particularly in rural areas. Maharashtra, Uttar Pradesh, and Rajasthan dominate in contributing in-migrants, emphasizing their pivotal roles. The study concludes by emphasizing the importance of considering gender-specific migration dynamics for informed policy interventions that address the diverse needs of both male and female migrants. This research contributes valuable insights for policymakers and scholars seeking a comprehensive understanding of migration dynamics, particularly the gendered perspectives, in the vibrant state of Gujarat.

Introduction

The movement of people within the boundaries of a country, is classified as internal migration whereas the process of movement of people away from national border, is called international migration(Rahul, 2022). The nature of migration process is selective. The selectivity is due to the differences between the individuals aspirations belonging to different groups. The most important differences are related to age, marital status, level of education, gender, socio-economic status, and housing situation. In case of migration selectivity is not only age based but also a gender based specific process(Khan et al., 2016). The role of gender, often relegated to the periphery in migration studies, is a crucial lens through which we can gain a deeper understanding of the social fabric woven by those who choose Gujarat as their destination. Gujarat, a crucible of cultural diversity and economic vibrancy, has become a magnet for individuals seeking opportunities, employment, and a new way of life. It has been reported in many studies that Gujarat is becoming the counter-magnet for the megacity like Mumbai, large number of migrants from the different states, like Rajasthan and Madhya Pradesh, Maharashtra, Chhattisgarh, Uttar Pradesh, Jharkhand, Bihar etc. where economic opportunities are rather limited (Shah and Dhak 2014) are attracted towards Gujarat. Also, the intra-state migration from less to more developed regions increased significantly as a result of increased connectivity and infrastructure within the state (Hirway et al., 2014). According to the census data on migration 2011, nearer to the half of the population of big cities composed of migrants including both the migrants from within the state and outside the state. Surat has the highest percentage of the internal migrants including both migrants from other states and from within the states. Ahmedabad is also one of the important city which attracts migrants. The major migrants sending states are Rajasthan, Uttar Pradesh and Maharashtra. The main reasons of migration that mentioned in the census are work employment and movement due to marriage (Half of the People in Gujarat's Big Cities Are Migrants | Ahmedabad News - Times of India, n.d.). Though there are large number of micro studies focusing on migration in Gujarat but less focus is on the gender-based migration study.

Objectives

The primary objective of this research is to unravel the often-overlooked gendered dimensions within the migration patterns to Gujarat. By delving into the dynamics of population movement, the study aims to shed light on how

gender influences and shapes the intricate narratives of migration. The study also intends to get information about the spatial analysis of migration across different districts in Gujarat.

Study Region

Gujarat is a state in India located on the western coast along the Arabian Sea. Gujarat is surrounded by the Indian states of Rajasthan to the north, Madhya Pradesh to the east, and Maharashtra to the southeast. It also shares international border with Pakistan in the northwest. Gujarat encircles the territory of Daman and Diu along with the Arabian Sea and shares a short portion of its southeast border with the Indian union territory of Dadra and Nagar Haveli. Gujarat has a 992-mile (1,596-kilometer) coastline. Gujarat is the ninth-most populous state, with a population of 60,439,692. The number of males is 31,491,260 and females is 28,948,432 according to the 2011 census data. The population density is 308 persons per square kilometre (800 persons/sq mi), lower than other Indian states. As per the census of 2011, the state has a sex ratio of 918 females for every 1000 males, one of the lowest (ranked 24) among the 29 states in India. In Gujarat, about three-fifths of the population lives in rural areas, however as urban areas have expanded, so the percentage of people living in rural areas has declined. The main concentration of population is in the eastern part of the state, in the plains surrounding the cities of Ahmadabad, Kheda, Vadodara, Surat, and Valsad; the region is both agriculturally productive and highly industrialized. There are also other population centres on the Kathiawar Peninsula, including on the southern shore between Mangrol and Mahuva, in the inland near Rajkot, and along the Gulf of Kachchh near Jamnagar. The population distribution rapidly declines towards the mountainous areas of eastern Gujarat and the northwest Kachchh district. The literacy rate of Gujarat is 79.31%. Gujarati is the official and primary language (Gujarat State Portal | All About Gujarat | Gujarat at a Glance, n.d.).

Database and Methodology

The present study is descriptive in nature. The study is based on the secondary sources of data. The census of India is the major source of information. The analysis of patterns of migration is based on the secondary source of data that is Census of India 2011. The data has been taken from the Migration Table (D series) of the census data and the place of last residence is taken into consideration for migration. Data based on the streams of migration like urban, rural and duration of migration have been carried out. The analysis and graphical representation of data has been done in excel.

Results and Discussions

Gender Disparity in the Volume of In-migrants to Gujarat

According to 2011 census, in total there are about 26.89 million migrants recorded in Gujarat as per their place of the last residence which forms nearly 45 percent of the total population of Gujarat. This all owing to the infrastructural and industrial development in Gujarat. Out of the total enumerated In-migrants i.e., 26,898,286 male in-migrants are 9,994,352 and female in-migrants are 16,903,934 females. In term of percentage males are 37 percent whereas females are 63 percent, suggesting a notable gender imbalance with a higher count of females. The In-migrants coming to rural and urban areas of Gujarat are 49 percent and 51 percent of the total In-migrants. Delving into the urban-rural breakdown, the total In-migrants enumerated in the rural area of Gujarat is 13,098,287, with 3,140,671 males and 9,957,616 females. In rural areas, the gender disparity leans towards females. In term of percentage the females are 76 percent of total migrants coming to rural areas. Conversely, the urban population of 13,799,999 exhibits a different pattern, with 6,853,681 males and 6,946,318 females. This indicates that urban areas attract a higher number of males. Males are dominated in all three basic industries like construction, textile and diamond industry the ratio of female workers is very less in these sectors (Hirway et al., 2014). These observations could be indicative of complex migration patterns, where males may be more inclined to migrate to urban centers for employment or other opportunities, leaving a higher proportion of females in rural settings.

The comprehensive analysis of in-migration patterns to the state of Gujarat delineates intriguing dynamics across various States and Union Territories (States/UTs). At the forefront, Maharashtra emerges as the primary contributor with 24.82% of the total in-migrant reported in the state of Gujarat, a substantial figure amounting to 971,975 individuals. Following closely by the state of Uttar Pradesh which contributes significantly with 23.73% in-migrants. The volume wise number is 929,411. According to a repot whenever a migrant from Uttar Pradesh visited their homes they bring their relative along with them to work in the textile industry the next important industry is diamond industry. Rajasthan, with 19.09%, constitutes another substantial share, which is 747,445 individuals enumerated in Gujarat. Migrants from the tribal areas of Rajasthan like Dungarpur and Banswara migrate to the state of Gujarat for work in constructional sites. Together, these three states form a significant portion, totaling 67.64% of the overall in-migrant population, indicating their pivotal roles as preferred origin place for those seeking

new opportunities, employment, and improved livelihoods. The main industries providing employment to migrants in Gujarat are construction industry, brick kiln industry, diamond cutting and polishing industry, textiles and power looms, and garments, engineering and electrical industries, domestic work, salt pan workers and other informal sectors(42 Lakh Migrants Have Made Gujarat Their Home | Ahmedabad News - Times of India, n.d.). Beyond these leading contributors, Bihar, Madhya Pradesh, Odisha, and West Bengal also play crucial roles in the intricate tapestry of in-migration, contributing to the overall diversity of population movement within the region. The other states are Bihar, Madhya Pradesh and Odisha. The odhiya workers are mainly engaged in the Surat power loom industries (Hirway et al., 2014). The complexity of these migration patterns underscores the interplay of diverse factors such as economic prospects, urbanization trends, and regional developmental disparities (**Fig.** 1 and **Table-**1).

Table-1: Gujarat: Percentage of In-migrants to Gujarat, 2011

State/UT's	Males	Females
Total In-Migrants	55.93	44.07
Maharashtra	46.34	53.66
Uttar Pradesh	64.61	35.39
Rajasthan	48.71	51.29
Bihar	70.28	29.72
Madhya Pradesh	49.37	50.63
Odisha	76.01	23.99
West Bengal	61.07	38.93
Jharkhand	77.33	22.67
Andhra Pradesh	50.91	49.09
Kerala	51.93	48.07
Remaining States/UT's	49.82	50.18

The analsis of in-migration patterns from States and Union Territories (States/UTs) reveals intriguing gender dynamics, showcasing variations in the male-to-female ratio among in-migrants. On an overall scale, in-migrants exhibit a slightly higher representation of males at 55.93%, compared to 44.07% females. Notably, Maharashtra demonstrates a gender distribution leaning toward females,

with 53.66%, while Uttar Pradesh sees a higher male representation at 64.61%. Rajasthan maintains a relatively balanced ratio, with 51.29% females. Bihar presents a significant gender disparity, with 70.28% males dominating the in-migrant population. Madhya Pradesh shows a nearly equal distribution, with 50.63% females. Odisha exhibits a substantial male majority at 76.01%, contrasting sharply with Jharkhand, where females constitute 77.33% of the in-migrants. West Bengal displays a more balanced representation, with 38.93% females. Andhra Pradesh, Kerala, and the remaining States/UTs exhibit fairly equal gender distribution patterns, with minor variations. This nuanced analysis underscores the importance of considering gender-specific patterns in understanding in-migration dynamics, potentially influencing policy considerations related to healthcare, education, and social services catering to the diverse needs of both male and female in-migrants (**Table-**2).

The analysis of In-migration across all the districts of Gujarat provides insights into the gender distribution among in-migrants, revealing distinct patterns in various locales. From the **Table-**2, it is clearly seen that there is dominance of male in-migrants in case of more urbanized districts like Surat, Ahmedabad, and the main reason behind this is the availability of male oriented wok and employment. Surat, with a total of 10,60,934 in-migrants, exhibits a male-dominated influx with 63.99%, whereas females constitute 36.01% of the migrant population. In contrast, Ahmadabad sees a more balanced gender distribution, with 52.38% males and 47.62% females among the total 3,79,097 in-migrants. Vadodara displays a slight female majority at 51.73% among its 1,33,451 in-migrants. Valsad follows a similar trend, with 55.49% males and 44.51% females among its 1,33,422 in-migrants. "Golden Corridor" is the industrialized center of state formed by the districts of Valsad and Vadodara. These are the fastest growing cities in Gujarat, one can see the boom in constructional activities there, lot of construction happening in the real estate & major infrastructure projects are being undertaken by private as well as public sectors, the people migrated here to work in the constructional sites, these districts are also known for their textile and the diamond industry. The women workers didn't get jobs in the large and medium diamond polishing units. They tend to work in the low-profile jobs, in constructional works, cotton fields etc. In the less urbanized area we find the dominance of females the major reason behind this is the marriages (Hirway et al., 2014). Banas Kantha and Sabar Kantha, however, portray significant gender disparities, with a notably higher percentage of females at 76.39% and 75.9%, respectively. The highest gap between male and

Table-2: Gujarat: Spatial Pattern of In-migrants to Gujarat, 2011

Sr. No.	Districts	Total In-Migrants	Males In-Migrants (Percent)	Females In-Migrants (Percent)

26	Porbandar	3,510	41.76	58.24

Source: Census of India,2011

female migrants recorded in the districts of Dohad, Patan and Banas kantha. These all are the bordering districts and share close connection with the bordering states and linked by the social and cultural ties. Bharuch, Jamnagar, and Navsari maintain a more balanced gender distribution, reflecting the diverse patterns in migration. Bhavnagar, on the other hand, stands out with a substantial male majority at 66.71%. Districts like Dohad and Patan exhibit pronounced gender imbalances, with 84.32% and 78.77% females among their respective in-migrant populations.

Conclusion

In conclusion, the study illuminates the intricate dynamics of migration to Gujarat, with a specific focus on gendered perspectives. The state's economic vibrancy and cultural diversity have attracted a significant influx of migrants, both from within and outside its borders. The migration patterns highlight Gujarat as a counter-magnet for individuals from states with limited economic opportunities. Gender disparities in migration are evident, with a higher representation of females in the overall In-migrant population. Urban areas, particularly districts like Surat, witness a male-dominated influx due to the availability of male-oriented employment. Conversely, less urbanized districts, especially those bordering other states, exhibit a notable dominance of females, often driven by marriage-related migration. Maharashtra, Uttar Pradesh, and Rajasthan emerge as primary contributors to Gujarat's In-migrant population, collectively playing a pivotal role in shaping migration dynamics. Further research and targeted studies on gender-specific migration dynamics can provide deeper insights for more refined policy interventions in the future.

BLOCK LEVEL DISPARITY OF HEALTH CARE FACILITY AND THE PERFORMANCE OF RURAL HEALTH CARE OF NORTH BENGAL, INDIA

Dr. Biswajit Das, Shantanu Paul, Goutam Mandal and Lamhu Dolma Tamang

Abstract

Health is one of the determining factors that can expedite the process of social and economic development of the nation. The general health condition of the people of an area is indicative of the quality of the health care facilities available in that area. The present study strives to analyse different dimensions of health care facilities to find out the status of health care system of North Bengal, India and assess the performance of the rural health care units. To do so, Health Care Facility Index (HCFI) has been measured to appraise the overall health care condition of North Bengal. The analysis estimates the efficiency of the healthcare system at block level using data of census 2011, district statistical hand book 2014 and State Bureau of Health Intelligence, Govt. of WB 2016-2017. The English Bazar block of Malda district has shown the height HCFI and Goalpokhar-I of North Dinajpur shows the minimum level of HCFI. There is a substantial difference in performance between these two blocks, resulting from inadequate utilization of available health care resources. The study also identifies complementarities of private health care resources and the role of other factors, such as Health Care Institution Population Ratio (HCIPR), Bed Population Ratio (BPR), Doctor Population Ratio (DPR), Doctor Health Care Institution Ratio (DHCIR) and Bed Health Care Institution Ratio (BHCIR). The results suggest a need for better utilization of budgetary resources to increase health infrastructure and manpower to improve the quality of rural healthcare through training and better management of resources in order to overall performance of the rural healthcare systems in North Bengal.

Introduction

"Health is a condition of complete physical, mental, and social well-being, not only the absence of sickness or disability," (World Health Organization, 1948). This definition explains the significance of health, which is seen as a fundamental human right and a key indication of human growth. In recent years, there has been

renewed emphasis on efficiency in resource utilization in the healthcare sector. A number of studies have focused on the overall performance of the healthcare system and its impact on health outcomes (Murray & Frenk 1999; World Health Organization [WHO] 2000). Some notable studies, for instance, have concentrated on hospitals, nursing homes, Health Maintenance Organizations (HMOs) and district health authorities (Wang, (1999); Sankar & Kathuria 2004). India had made remarkable progress in the field of health. The first important initiative was made in 1943, by Health Survey and Development Committee Report and known as Bhore Committee (KPMG and ASSOCHAM, 2011). It was a detailed plan for healthcare in the country. The initiatives' list included the adoption of a National Health Policy in 1983, the 73rd and 74th Constitutional Amendments devolving power to local institutions in 1992, the National Nutrition Policy in 1993, the National Policy on Indian System of Medicine and Homeopathy and Drug Policy in 2002, introduction of a first health insurance schemes for poor people in 2003 and the inclusion of health in the Common Minimum Program of Government in 2004.

In order to improve the National Health System of India it is therefore necessary to evaluate and assess the health services in terms of quantity, quality, cost and sustainability (Capolongo et al. 2016b, 2015a). Moreover, most important aspects is the adjusting service delivery structures to meet the health needs of the population in terms of quantities and modalities of networked, affordable and sustainable evidence based services (Buffoli et al. 2015) and modernizing outdated structures. Currently India has 0.6 beds every 1,000 inhabitants. This scenario is worsened by the scarcity of architectures for health and support staff that leads to have 50% of beds in the public health sector and 30% in the private one not utilized totally. Nevertheless, the situation has, however, slightly improved by NRHM, founded by 85% the Union and the remaining 15% by the states, which aims to bring its action in rural areas strategic, engaging more than 800,000 workers paid according to the performances Capolongo S, B. M. (2015a). The public health is mainly guaranteed by primary levels, with differences between rural and urban areas; in urban areas there is a double level system: a Basic Health Post for few thousand inhabitants and a Health Centre Urban, or Urban Family Welfare Centre, for 100,000 people attached with a general hospital. Instead, in rural areas there is a triple level system: a Sub-Centre for 5,000 inhabitants manages by two professionals (a man and a woman); a Primary Health Care Centre for 30,000 people with medical and paramedical staffs; a Primary Hospital with 30 beds per 100,000 inhabitants and some basic specializations (WHO, India 2012). The last cases include primary care services, which mean that they are specialized, mainly, in vaccinations,

prevention of malnutrition, pregnancies, postnatal care and treatment of common diseases. The public health infrastructure in West Bengal area is wide covering even in the remotest villages. As HOPE Annual NGO Report reported, there are 9 Medical College Hospitals, 16 District Hospitals, 45 Sub divisional Hospitals, 346 Community Health Centers, 922 Primary Health Centers and 10.356 Sub-Centers across West Bengal (HOPE, 2014). More recent data, by Ministry of Health and Family Welfare, estimate that there is a rise in health Infrastructure: 13,186 Sub-Centers, 2,166 Primary Health Center and 541 Community Health Center. However, the level of welfare seems to be very poor in the entire region (Ministry of Health and Family Welfare, 2015). The healthcare system has a primary healthcare network, a secondary care system comprising district and sub□divisional hospitals and tertiary hospitals providing specialty and super specialty care. Each of the nineteen districts is coordinated by a Chief Medical Officer of Health (CMOH), together with Deputy and Assistant CMOHs, whose responsibility is to manage the primary health care and to ensure the effective implementation of the various medical, health and family welfare programs (Rebecchi, 2018).

The secondary level hospitals are managed by medically trained Superintendents, who directly report to the CMOH, all the useful information and take part into a hospital management committee. In addition, there is the Block Medical Officer, who is responsible for providing services, monitoring and supervising the primary health centres and health program implementation. The third level hospital is referred by two levels before; its specialist care needs to be identified and then patients can be directed to specialized departments. West Bengal Health Service provides the health care professionals for the state wide infrastructure, while Medical Education Service employs teachers at the training institutions (Office of the Registrar General and Census Commissioner, 2011). In general, the community based primary healthcare services have been formulated with the objective of bringing an overall improvement in the urban health scenario in West Bengal; 62 urban local bodies have completed training of honorary health workers. Ministry of Health and Family Welfare of the Government of West Bengal is responsible for healthcare administration in the region. The program budget for two years (2020-2021) was around ₹11,280 crore (US$1.4 billion, Ministry of Health &Family Welfare, West Bengal, 2022). The current study aims to examine the health-care facility system in the North Bengal districts of West Bengal on a block wise to see the disparity among the block in terms of health care facility and their performance.

Objectives

(1) To determine the block wise disparities in health care facilities in all Districts of North Bengal.

(2) To assess the block wise performance of Rural Health Care Facilities of North Bengal.

Study Region

North Bengal is a region located in the northern part of the Indian state of West Bengal. It is renowned for its breath-taking natural beauty, varied flora and wildlife, and extensive cultural history. The region is bounded by the lofty Eastern Himalayas in the north, and it shares its borders with countries like Nepal, Bhutan, and Bangladesh. The study area extends from approximately 24°40'20"N to 27°13'N latitude and 87°45'50"E to 89°53'E longitude. North Bengal consists of eight districts, namely Cooch Behar, Alipurduar, Jalpaiguri, Kalimpong, Darjeeling, Uttar Dinajpur, Dakshin Dinajpur, and Malda. It is characterized by a division into two distinct geographical zones. The northern part is classified as the Sub-Himalayan Zone, while the southern part is composed of sediment and debris brought by rivers descending from the slopes of the Himalayas. Consequently, except for the northern fringe, the entire region consists of plains. Numerous rivers, including the Teesta, Torsha, Jaldhaka, Raidak, Sankosh, Mahananda, Punarbhaba, Atrai, and Kulik, drain the study area. The climate in the study area is characterized by hot, humid conditions and heavy rainfall, although the northern hilly areas experience a cooler climate. The region is also home to diverse species of fauna and flora. This region is characterized by its diverse physical and socio-cultural aspects, displaying notable variations in economic and human development across the districts. It covers an area of 21,855 square kilometres, which accounts for 24.62% of the state's geographical area. According to the 2011 census total population of the region were 17291050, which were 18.83% of the state's total population, with a higher concentration of Scheduled Caste (SC) and Scheduled Tribe (ST) populations, as well as a significant influx of immigrants. The region has a total of 462 healthcare institutions with 13949 beds and 1628 registered doctor's facilities only, which is not sufficient to cater to the present population.

Materials and Methods

The present study is fully based on secondary database, gleaned from District level Census report, 2011, State Bureau of Health Intelligence,

Govt. of WB 2016-2017 and District Statistical Handbooks, 2014 of eight districts i.e., Alipurduar, Cooch Behar, Darjeeling, Jalpaiguri, Kalimpong, Malda, North and South Dinajpur of North Bengal. In order to compute the Health Care Facility Index, block level total population, numbers of health care institutions (both public and private), total number of beds and total number of doctors have been collected for total 69 blocks of North Bengal region. All the Hospitals including Rural Hospitals, Block Primary Health Centres (BPHC), Primary Health Centres (PHC), other clinical Departments of Govt. of West Bengal including State Govt. Undertakings, Local Bodies, and Govt. of India including Central Govt. undertaking, N.G.O. / Private Bodies (Nursing Homes) have been considered as Health Care Institutions (HCI). Total number of beds and total number of Doctors of each C. D. Blocks have been collected from District Statistical Handbooks of Eight Selected District, 2014 (Census, 2011; District Statistical Handbooks, 2014). The Health Care Facility Index (HCFI) is a combination of five selected dimensions. These dimensions have been calculated on the basis of above-mentioned data for each block it includes – Health Care Institution Population Ratio (HCIPR), Bed Population Ratio (BPR), Doctor Population Ratio (DPR), Doctor Health Care Institution Ratio (DHCIR) and Bed Health Care Institution Ratio (BHCIR). The HCIPR dimension/indicator is used to find out the number of health care institutions to serve one lakh population in the region. Bed Population Ratio or BPR is used to measure the number of beds available per 10000 populations in the study area. On the other hand, the Doctor Population Ratio or DPR helps to indicate the number of doctors per one lakh population in the region. The DHCIR dimension/indicator is used to find out the number of doctors per health care institution and the last dimension i.e., Bed Health Care Institution Ratio or BHCIR is used to measure the number of beds per health care institution in the study area. The following formulas have been incorporated to measure the above-mentioned dimensions/indicators for health care facility system-

$$HCIPR = \frac{Health\,Care\,Institution\,(HCI) \times 1,00,000}{Total\,Population} \tag{1}$$

$$BPR = \frac{Number\,of\,\,Beds\,in\,HCI \times 10,000}{Total\,Population} \tag{2}$$

$$DPR = \frac{Number\,of\,\,Doctors\,in\,HCI \times 1,00,000}{Total\,Population} \tag{3}$$

$$DHCIR = \frac{Number\ of\ Doctors\ in\ HCIs}{Number\ of\ HCIs} \quad (4)$$

$$BHCIR = \frac{Number\ of\ Beds\ in\ HCIs}{Number\ of\ HCIs} \quad (5)$$

After calculating the ratio of the five variables the values of each indicator are first normalized to an index value of 0 to 1, using Dimension Index formula. With the actual value for a given block, and the overall maximum and minimum, the dimension (indices) value for each metric is calculated as:

$$HFCI = \frac{A_i - m_i}{M_i - m_i}$$

Where,

d_i = Dimension index of ith dimension,

A_i = Actual Value of ith dimension,

M_i = Maximum value of ith dimension and

m_i = Minimum value of ith dimension.

Now, in order to measure the Health Care Facility Index for each block of North Bengal the composite index has been calculated using the five mentioned indicators. The formula used in the UNDP Goal Post technique uses minimum and maximum values that have been specified. However, in this technique, we have taken into account the observed minimum and maximum values for each dimension. According to Goel and Sharma (2017), the dimension's value (*di*) is between *0* and *1*. The success of the C.D. Blocks/Municipal Corporation is predicted to be higher in the i^{th} dimension by a high dimensional value (*di*). Considering all the five dimensions, i^{th} C. D. Block can be represented by a point (d_1, d_2, d_3) in three-dimensional Cartesian space like $0 \leq d_1, d_2, d_3 \leq 1$. In the three-dimensional Cartesian space, the point '*0*' would indicate the worst condition whereas '*1*' would indicate the ideal or perfect condition. HCFI is measured by the normalized inverse Euclidean distance of the point (d_1, d_2, d_3) from the best or perfect point.

$$HFCI = 1 - \sqrt{\frac{(1-d_1)^2 + (1-d_2)^2 + (1-d_3)^2 \ldots}{5}}$$

The value of HCFI ranges from '*0*' to '*1*'. The value '0' indicates the worst health care facilities system and '*1*' indicates the Perfect health care facilities. On the basis of the HCFI values, the C. D. Blocks of North Bengal region are classified into three categories. The range $0.5<HCFI\leq1$ indicates 'High' or 'Very Good' health care facility system; $0.2<HCFI\leq0.5$ indicates 'Moderate' health care facility system and $0<HCFI\leq0.2$ 'Low' or 'Poor' health quality facility system.

Result and Discussion

Health Care Institution Population Ratio (HCIPR): The population serviced by a single healthcare facility in the research area is determined using this dimension. In this dimension, Matigara C.D. Block of Darjeeling District is in the best position, while Goalpokhar-I of North Dinajpur District is in the worst. Bed Population Ratio (BPR): The bed population ratio is used to calculate how many beds are available for every 10,000 people. In North Bengal region, the greatest BPR is found in the Kurseong block of Darjeeling District, while the lowest BPR is observed in Goalpokhar-I of North Dinajpur District (**Table-**1).

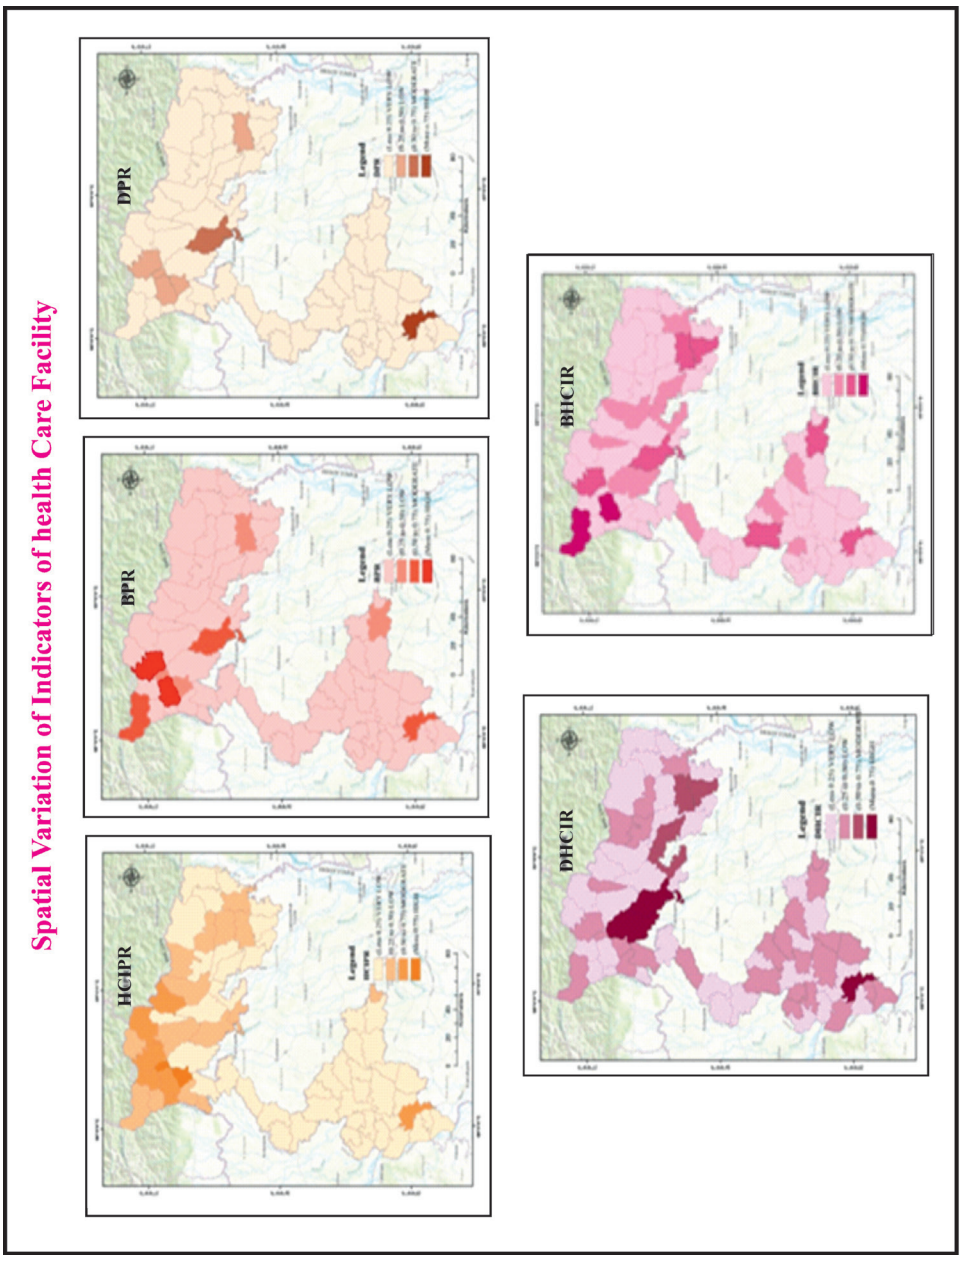
Table-1: Health Care Facility Dimensions of North Bengal

Dimensions	Goalposts of the Dimensions			
	Maximum Value		Minimum Value	
Health Care Institution Population Ratio (HCIPR)	10.17	Matigara	0.61	Goalpokhar I
Bed Population Ratio (BPR)	40.50	Kurseong	1.23	Goalpokhar I
Doctor Population Ratio (DPR)	55.61	English Bazar	0.99	Itahar
Doctor Health Care Institution Ratio (DHCIR)	9.54	English Bazar	0.25	Rangli Rangliot
Bed Health Care Institution Ratio (BHCIR)	78.25	Darjeeling Pulbazar	8.00	Tufanganj II

Sources: (1) District Statistical Handbooks, 2014, Census, 2011;

(2) Computed by the Authors

Doctor Population Ratio: The number of doctors per lakh of people in the study region is indicated by this dimension. According to the Planning Commission of India's 2011 report, the doctor population ratio should be 1 doctor per 1000 people (**Fig.** 1). However, in North Bengal as a whole, none of the blocks can reach this crucial DPR threshold. The lowest DPR is found in Itahar block of



Spatial Variation of Indicators of health Care Facility
DPR

HGIPR
BHCIR
DHCIR

Fig. 1

North Dinajpur District, while the highest DPR is observed in English Bazar block of Maldah District (**Fig.** 1).

Doctor Health Care Institution Ratio: To determine the number of doctors per healthcare facility in the study area, this dimension is used. After analysing the dataset, it is observed that Rangli Rangliot block of Darjeeling District has the poorest DHICR conditions in the entire North Bengal, whereas English Bazar C.D. block of Maldah District has the maximum number of doctors per institution.

Bed Health Care Institution Ratio: In the study area, this dimension is used to calculate the average number of beds per healthcare facility. The more beds in a hospital means the better for the local people and shows the better healthcare facilities. Tufanganj II in Cooch Behar District has the minimum number of beds per institution whereas Pulbazar in Darjeeling District has the maximum number of beds per institution.

Health Care Institution Population Ratio: This indicates Health Care Institution Population Ratio which is one of the five main indicators of the Health Care Index. Based on the ratio of the HCIPR it is observed that Matigara block of Darjeeling district is in the top with index value 1 and Goalpokhar-I of North Dinajpur district has the lowest index value of 0. Based on the index values all the blocks have been categorized in four parts. Very low having the index value of 0 to 0.25, low 0.25 to 0.50, moderate 0.50 to 0.75 and last one is high more than 0.75 value. The map revels out of the total 68 blocks 46 blocks are comes under very low category which is 67.64 percent of the total block of the entire region all the blocks of Uttar Dinajpur and Dakshin Dinajpur. Low HCIPR has been recorded in 15 blocks out of 69 and it consists of 22.06 percent. Rest 7 blocks has been recorded as moderate HCIPR which comprise 10.29 percent of the total blocks and out of the 7 blocks 5 are from Darjeeling district which shows that Darjeeling district has the good health care institution as per their total population. High HCIPR is recorded in Matigara block which is again in the Darjeeling District. So, the map indicates that with in the north Bengal part out of the 8 district only Darjeeling district has the proper population and health care Institution ration, the main reason behind is that the biggest city of the north Bengal Siliguri. Siliguri has a quit large number of the private health care institution as the population is high of the city and the hinterland of the city also huge. There is few private super-speciality Hospital also functioning.

Bed Population Ratio: The bed population ratio is used to calculate how many beds are available for every 10,000 people. In North Bengal region, the greatest

BPR in the Kurseong Block of Darjeeling District, while the lowest BPR is observed in Goalpokhar-I block of the North Dinajpur District. The BPR ratio has been normalized based on the dimension index prescribed by UN in the HDI index. All the dimension index values of the BPR is categorized in four parts. Very low index value having less than 0.25, low (0.25 to 0.50), Moderate (0.50 to 0.75) and High more than 0.75 index value. The maps revels that out of the 68 blocks of North Bengal 61 come under very low BPR index which comprises 89.70 percent of the total blocks. Rest 10 percent are from the three different categories. Balurghat block of South Dinajpur, Cooch Behar- I block of Cooch Behar District and Matigara block of Darjeeling district shows low BPR index which comprises 4.41 percent of the total number of the blocks. Moderate BPR index has been found English Bazar block of Malda District, Jalpaiguri Sadar of Jalpaiguri District and Pulbazar block of Darjeeling district. All the six blocks are very close to their district town and some blocks surrounded the district town because of that the BPR index is much higher from the other blocks. Kalimpong Block of newly formed Kalimpong district and Kurseong block of Darjeeling district has the highest value in terms of the BPR index and both fall under the high BPR.

Doctor Population Ratio: The number of doctors per lakh of people in the study region is indicated by this dimension. According to the Planning Commission of India's 2011 report, the doctor population ratio should be 1 doctor per 1000 people. However, in North Bengal as a whole, none of the blocks can reach this crucial BPR threshold. The highest DPR in North Dinajpur District is in Itahar block, while the lowest DPR is in English Bazar in Malda District. From the map of DPR it is observed that 62 blocks out of 69 blocks of North Bengal is under very low (<0.25) category which is comprise 91.17 percent of the total blocks. Only four blocks fall under low (0.25-0.50) category. Jalpaiguri Sadar block of Jalpaiguri district comes under moderate DPR and English Bazar block of Malda district has the high DPR in the entire North Bengal which shows the actual condition of the health care facility.

Doctor Health Care Institution Ratio: To determine the number of doctors per healthcare facility in the study area, this dimension is used. After analysing the dataset, we have discovered that Rangli Rangliot in Darjeeling District has the poorest conditions in North Bengal, whereas English Bazar C.D. Block in Maldah District has the maximum number of doctors per institution. DHCIR ratio again used for the dimension reduction and the values of the dimension index has been categorized in four categories similar to the other dimension as very low, low, moderate and high with the same value rage of the index value to compare with the other indicators and

based on the dimension index value the map has 0 been prepared. Bed Health Care Institution Ratio (BHCIR): In the study area, this dimension is used to calculate the average number of beds per healthcare facility. The more beds a hospital has, the better off the local healthcare facilities are. Tufanganj II in Cooch Behar District has the lowest Bed per health care institution while Pulbazar in Darjeeling District has the highest beds per health care institution (**Fig.** 2).

The map revels that 35 blocks out of the 69 blocks of North Bengal have fall under the category of very low index (<0.25) which indicates 51.47 percent. 27 blocks out of the 68 blocks of the North Bengal are comes under the low (0.25-0.50) category as per the dimension index which comprise 39.70 percent and Moderate DHCIR is observed only in four blocks and all the four blocks are from Cooch Behar District. High (>0.75) DHCIR has been observed only in the rest 3 blocks out of the three 2 from Jalpaiguri District and one from Malda District. From the calculated ratio of the bed per health care also go through the process of the dimension reduction using the dimension index to compare with the other dimension of the health care facilities and the dimension index has been categorized in to the four category, very low (<0.25), low (0.25-0.50), moderate (0.5-0.75) and high (>0.75). Best on the dimension index value the map has been prepared. From the map it is observed that very low index has been found among 50 blocks out of the 69 blocks which comprises 73.53 percent of the blocks. Ten blocks out of 68 have fall under low BHCIR index which comprise 14.70 percent of the total blocks. Moderate BHCIR index is observed in the 8 blocks and only Pulbazar block of Darjeeling district has the highest number of beds per health care institution The above map (**Fig.** 2) indicates the healthcare facility of North Bengal. Similar to the other indices health care facility also categorised into four categories based on the index value which various from 0 to 1. Out of 69 blocks 52 blocks have shown the very low health care facility (less than 0.25) which is 75.36 percent of the total blocks of North Bengal. After calculating the district level health care as a whole it shows the worse condition in Malda and Uttar Dinajpur district are really in a very poor condition followed by the Dakshin Dinajpur and Darjeeling district has the better health care facility among the eight districts of North Bengal followed by Jalpaiguri and Cooch Behar. Low health care facility (0.25 to 0.50) has been observed among the 15 blocks out of 69 which comprises 21.73 percent of overall blocks. Out of the 15 blocks 5 blocks from Cooch Behar which is one third of the total, 3 block from Darjeeling, 2 each from Alipurduar and Dakshin Dinajpur. There is not a single block from Malda district in the low health care facility.

Only 3 blocks out of the 69 blocks of North Bengal are fall under the moderate health care facilities (0.50 to 0.75) which comprises 4.34 percent. These three blocks are from three districts, Kalimpong I (0.54) block from Kalimpong district, Jalpaiguri Sadar Block (0.59) of Jalpaiguri district and English Bazar (0.65) of Malda District are under this category. There is no single block has found with high health care facility with more than 0.75 index value which show the real face of the health care facility of the region (**Table-**2).

Performance of Rural Health Care Units

There are several ways for the assessment of the performance of the health care facilities but in the study simply few parameters have been taken into consideration which is given by the government in their report. For assessing the health care facility here Bed Turn over rate, Bed Occupancy Rate, Average length of stay in hospital, outpatient per day, percentage of deliveries to admission, percentage of emergency admission, percentage of imaging and electro medical test, percentage of laboratory test, and percentage of patient referred to the other hospital these

nine parameters has been taken into consideration. The information related to the performance of rural health care facilities have stated. Bed Turn Over rate (BTR) is maximum in Kaliachak-III (690.2) block of Malda District and Minimum in Rangli Rangliot Block (13.9) in Darjeeling District which indicates the number of patients treated per bed in the specific year (2016-2017) is maximum in Kaliachak-III as compare to the other block of North Bengal. The Bed Turnover Rate is a measure of productivity of Hospital beds. Out of the eight districts of North Bengal, Malda (318.65) is in the 1st rank in BTR followed by Jalpaiguri (168.66) and North Dinajpur (157.42) and lowest BTR is observed by the Kalimpong district (20.63) as Kalimpong is a newly formed district with low population and a smaller number of rural hospital and other health care facilities. Hospital Bed Occupancy Rate means the number of beds occupied for the treatment of the patient divided by the total number of beds over a specific year multiplied by 100. So, in terms of the BOR Rajganj block (460.5) of Jalpaiguri district is in the first rank followed by Nagrakata (445.5) of same district, Kaliachak-III (267.1) and Manikchak (243.1) of Malda district which indicates the patients pressure is very high in these blocks whereas Tapan (6.1), and Banshihari (8.9) block of South Dinajpur show the very low Bed Occupancy Rate as the health care facility is not good of these block so they prefer to go other hospital and the number of bed and hospital in this block also very few in number.

Average length of stay in hospital is another important parameter to assess the performance of health care facility. Average length of stay is mainly depended on the facility and care provided by the health care unit like number of beds, availability of doctors and admission facility and more over to deal with little complicated illness. Average length of stay is maximum in Falakata block (5.7) of Alipurduar district followed by Kalimpong-I and Gorubathan block of Kalimpong district and minimum length of stay in hospital has been observed in Harirampur block (0.2) of South Dinajpur. Percentage of the patient taken admission of delivery is one om the other important parameters of the study. It is observed that Kaliachak-I block of Malda district has the highest percentage of admission related to delivery (47.2%) followed by Chopra (43.9%), Raiganj (41.50%) block of North Dinajpur district (Appendix-3). Although the health care facility of these blocks are not good as these blocks fall under very low health care facility (**Fig.** 2) but due to population pressure the admission percentage is high. On the other hand, Kalimpong-II and Garubathan block has the lowest percentage of admission related to delivery. District wise Malda is in the height rank followed by North Dinajpur main reason behind it

as per the 2011 census birth rate and growth rate of population in high in these two districts of North Bengal. Similarly in terms of the emergency admission in health centre is maximum in these two districts. Karandighi block of North Dinajpur is high in terms of emergency admission in hospital followed by Harischandrapur-I and Raiganj block and minimum percentage of emergency admission has reported in Madarihat block (0.1%) followed by Cooch Behar-I block. Percentage of Imaging and Electro Medical tests are very low in all the blocks of North Bengal, in Alipurduar district only Falakata has reported 0.6% of imaging and eletro medical test and rest other blocks hospital do not have this kind of facilities. Similarly in Cooch Behar, North Dinajpur and South Dinajpur district reported one hospital each with this kind of facility. So the study shows that imaging and electro medical test is not much available in the rural hospital of north Bengal for this service people has to depend on the district of subdivisional hospital. Percentage of Laboratory test also shows the similar type of result but as compare to the imaging and electro medical tests laboratory test is quite higher. Percentage of laboratory test is maximum in Madarihat block of Alipurduar district as Madarihat block hospital is the only hospital in the entire block so the pressure is huge and on the other hand Cooch Behar-II block is nearer to the district hospital so most of the people goes to district hospital than the rural block hospital so it recorded the minimum laboratory test and there are so many blocks shows zero value which mean the imaging and laboratory test facility is not there in those blocks. Percentage of patient refer to the other hospital to discharge patient indicates that height refer percentage is found in Kalimpong district followed by Alipurduar district and lowest refer rate is observed in Malda district. Kalimpong -II and Garubathan has the maximum percentage of refer to the other hospital, the main reason to refer the patient is lack of medical facility in these blocks as per the health care facility map (map3) shows that both the block fall under the very poor category in terms of health care facility.

Conclusion

This paper has attempted to show the health facilities and challenges in North Bengal where the problem of providing effective health care services to the majority of its citizens has become an impossible task. Rural health services which form the backbone of public health system, is lacking in basic infrastructure, staff and essential medicines. The sufficient manpower is an important prerequisite for the efficient functioning of the Rural Health Infrastructure. Health indicators are very poor and the poor face financial ruin if visited by a serious health event. India is committed to the goal ‘health for all’ and in the last four decades, a wide network

of primary health centres and sub-centres has been created. Yet most of the states including West Bengal are far away from this goal. One of the fundamental metrics for assessing a society's well-being is the availability of health care. The health care system in North Bengal has been evaluated in this study by measuring several aspects of healthcare services. Each Block's Health Care Facility Index (HCFI) rating reflects the state of the healthcare facilities there as well as their location within the district. The average HCFI score for North Bengal is 0.19, which suggests that the majority of Districts have modest to subpar health care services. The HCFI of North Bengal, on the other hand, has a standard deviation value of 0.14, indicating that all Districts have moderately good health care services. Among all districts of North Bengal, the mean value is highest in Bed Health Care Institution Ratio, 23.38 whereas Health Care Institution Population Ratio and Doctor Health Care Institution Ratio is lowest like 2.81 and 2.87.

The number of beds in health care institutions per 10000 populations is not better numbered in all districts of North Bengal with 7.32/10000 population. The average Doctor Population Ratio is 8.03 in all Districts per one lakh population is not better in North Bengal. But at present, medical facility offered by Darjeeling is no match for its past glory. Since Darjeeling is the district headquarter Sadar or District Hospital is located here. However, the condition of these 308 bedded hospitals needs much improvement. Now hospital offers quality services to the resident of Darjeeling and their surroundings. As the regional headquarters of the Jalpaiguri district, the city of Jalpaiguri has a prominent position in North Bengal. The nearby population in the region often flocks to the city to get proper health care services. This position is amplified by the systemic industrial development of the district and rapid influx of people who needs proportionate medical care. Healthcare Facilities in Cooch Behar is quite effective with number of hospitals, path-labs, chemist shops and allied medical services. The citizens of the city enjoy well administered and well provided health services. Healthcare facilities in Cooch Behar are at par with other metro cities of West Bengal. But the problem of the health care facility in north Bengal is it mainly concentrated in the district town or particular in the blocks which are nearer to the main tow. The main problem is for the people who stayed in the blocks which is far from the district town so they could not access the medical facility due to their locational disadvantage for that parity should be there to improve the infrastructure for all the block hospital instant of concentrating a particular hospital or health centre. Although the government has taken initiation to improve the rural health care by

National Rural Health Mission which contribute a lot but it is not sufficient. Since the development of a region's health care facilities is intimately related to the wellness of that society, the government may seek for a strategy to raise the standard of those facilities from the ground up. Apart from economic condition, the social hierarchy or the system of social stratification existing in the society of West Bengal is likely to influence the health behaviour of individuals. Social stratification system determines the living conditions, privileges, obligations and cultural traditions surrounding the life of a person which in turn affect his perceptions regarding health, knowledge of health care and accessibility to health resources (SNM Kopparty, 1994). Who is responsible for this dilapidated health structure of North Bengal? This question echoes in the panorama of the broken health structure of the North Bengal.

CROP REGIONS IN TUNGABHADRA RIVER BASIN IN KURNOOL DISTRICT, ANDHARA PRADESH

B. Appanna and Dr. Y. Sujatha

Abstract

The current study focuses on the regionalization of crops in the Tungabhadra River basin of Kurnool District. The basin is characterized by a rural population, and agriculture serves as the primary source of livelihood for the inhabitants due to the lack of an industrial base. Traditional and subsistence agricultural practices have been prevalent in the basin for a long time. The basin consists of 45% block cotton soil and 30% red soil. Primarily farmers are cultivating this area like commercial crops, particularly cotton and groundnut, along with food grains such as bengal gram, red gram, fruits, and vegetables. The choice of crops grown in the basin during an agricultural year is greatly influenced by physiographic, climatic, soil, and socio-economic conditions, as well as the people's are following traditional agricultural practices. As a result, specific crop regions have emerged in the basin. The study also examines the spatial variation at the mandal level in terms of temporal change, using data from two periods: 2009–10 and 2019–20. This paper aims to calculate and delineate crop regions based on a ranking method.

Introduction

The Tungabhadra River basin is located in the western part of the Kurnool district; it is characterized by its unique agricultural landscape. More than 75% of the region comprises Pedi plains, with 45% of the soil being cotton-rich block soils and 35 % of being red soils due to its geological connection to granite and gneisses. The primary mode of agriculture in this region is rain-fed, and agriculture stands as the predominant land use. Over 70% of the population relies on agriculture for their livelihoods. However, the agricultural system here is primarily based on traditional practices and operates at a subsistence level due to the limited availability of irrigation facilities and the prevalence of marginal and small landholdings. A significant portion of the working population is engaged in agricultural labor. In this particular context, the examination of crop regionalization assumes a crucial role in evaluating the arrangement and

distribution of crops across the basin. The concept of crop regionalization holds integral and significant within the realm of agricultural geography. Krishnakumari has expressed the view that the identification and demarcation of crop regions are immensely beneficial in the context of regional agricultural planning, particularly in optimizing crop cultivation. Agricultural regionalization holds a long-standing position in the field of agricultural classification and plays a crucial role in the planning and advancement of agriculture in developing nations. It serves as a tool to group together various agricultural phenomena, both apparent and hidden, across the Earth's surface. This tool allows geographers to partition an area into multiple regions based on the diversity found within the agricultural system. Moreover, it provides valuable insights into the spatial distribution of crops at a regional level (Dayalan, 2018). Therefore, a systematic investigation of agricultural regions based on crop associations is imperative for geographers as an initial step towards comprehensively understanding the Agricultural geography of the region. Ultimately, this aids in the planning and development of crops at a regional level. The objective of the present study is to identify the major crop regions in the Tungabhadra River basin of Kurnool district. The ranking method was employed to delineate the crop regions into primary (first rank), secondary (second rank), and tertiary (third rank) categories. The first three crops, regardless of their percentage of occupation were selected for the purpose of crop regionalization analysis. Given that the basin falls within a semi-arid climatic zone, effective planning is a great significance, and the present study sheds light on this aspect.

Study Region

The study area of the Tungabhadra River basin is in the north-western region of the Kurnool district in the state of Andhra Pradesh, India. It lies between North Latitude 15°15'00" to 16°'00" and East Longitude 77°0'0" to 78°15'00". The area falls within the Survey of India (SOI) Toposheet Nos. 57E/1 to 57E/16 and 57I/1 to 57I/5. The total area of the basin is 6,934 square kilometers. The basin consists of 30 mandals, with 21 mandals fully covered and the remaining 9 mandals partially covered. The basin receives an average annual rainfall of 670 mm and experiences temperatures ranging from 26°C to 46°C in the summer and 12°C to 31°C in the winter. The northwestern portion, which includes Adoni, Peddakadubur, Alur, Aspari, Chippagiri, Halaharvi, Holagunda, Pathikonda, Devanakonda, Krishnagiri, Veldurthy, Kodumur, and Kallur mandals, has a desolate appearance with vegetation mostly limited to small pockets of reserve forests. This portion of the basin covers an area of 41,712 hectares, which accounts for 4.46% of the total geographical area.

The terrain in this region slopes from south to north and is drained by the river Hundri, which joins the river Tungabhadra at Kurnool. The soils in the northwestern parts traversed by the river Hundri are black cotton, while the southeastern parts are predominantly pure red soils. Geologically, the basin is underlain by the crystalline rock of the Peninsular Gneissic Complex (PGC), which includes the granite gneisses and granite in the western and southern parts of the basin.

Objectives

(1) To identify and demarcate the crop regions, such as First, Second, and Third ranking crop regions, of the Tungabhadra River Basin for the years 2009–10 and 2018–19.

(2) To study the changes in crop regions during a 10-year period.

Data and Methodology

The current study has collected secondary data from the Chief Planning Officer (C.P.O.), Handbook of Statistics, Kurnool district, focusing on the general cropping pattern for two specific time periods: 2009–10 and 2019–20. The data has been collected at the 'Mandal' level, ensuring a comprehensive analysis. The data has been analyzed using basic statistical techniques such as percentages and averages. The objective of the study is to investigate the spatial patterns of crops that are ranked from first to third in terms of the percentage of the total cropped area, with a specific focus on First, second, and third crop regions. The first-order crop regions, which are those with the highest ranking, have been identified by considering the crops that contribute the highest percentage to the total cropped area in each of the component area units, regardless of their overall percentage. Similarly, second-order and third-order crop regions have been delineated based on their ranking in terms of percentage. In order to accomplish the objectives of the study, the percentages of different crops cultivated in the basin have been calculated and organized in descending order to define the crop regions.

Results and Discussions

First ranking crop regions or first order crop regions (2009-10)

Out of the 30 mandals, 11 mandals have groundnut as first-order crops, 10 mandals have bengal gram as first-order crop, 5 mandals have cotton as first-order crop, 2 mandals have red gram as first-order crop, 1 mandal has paddy as first-order crop, and one mandal has fruits and vegetables as first-order crops.

Groundnut and Bengal gram Region

Groundnut is the leading crop cultivated in the basin, with its cultivation spread across 11 mandals. The favorable environmental conditions in the basin have proven to be advantageous for the growth of groundnut, particularly on light mixed red and block soils. The distribution of groundnut cultivation is predominantly concentrated in the southern and central regions of the basin. It is the basin's second-largest crop cultivated as the first-ranking crop, next only to groundnut. Within the basin, it holds the top position in 10 mandals, namely Kurnool, Kallur, Orvakal, Kodumur, Gudur, Nanikotukur, Miduthur, Alur, Aspari, and Maddikera. The distribution of these mandals is predominantly concentrated in the northeastern and southwestern parts of the basin.

Cotton, Red gram Region

Cotton is the third most significant first-ranking crop cultivated in 5 mandals, namely Adoni, Kowthalam, Nandavaram, Mantralayam, and Holagunda. These mandals are primarily concentrated in the northwestern region of the basin. Red gram crop farming was limited to only 2 mandals, namely Bethamcherla and J. Bunglow.

Paddy and Fruits and vegetable Region

These are too tiny in their extent, as they comprise of 1 mandal each, i.e., paddy in Pagidayala mandal and fruits and vegetable crops in C. Belagal mandal.

First ranking crop regions or first order crop regions (2019-20)

In the year 2019–20, a total of 5 crops were observed in the primary crop regions, each with varying degrees of prominence. Among these regions, the cotton crop region stood out as the largest primary crop region, with 16 mandals. Followed by the Bengal gram region with 5 mandals, the red gram region with 4 mandals, the maize region with 3 mandals, and finally, the groundnut region with 2 mandals.

Groundnut, Bengal Gram and Cotton Region

As a first-ranking crop region, the groundnut crop is registered in two mandals, respectively, Krishnagiri and Tuggali mandals. Bengal Gram region is the 2nd largest first ranking crop region in Tungabhadra River basin during 2019–20, occupying five mandals located in a few mandals in the north-east and western mandals of the basin. The cotton crop is the dominant primary crop region among all other crops, and it was the first-ranking crop in 16 mandals.

It emerged as the largest crop region in the study area during 2019–20. Their concentration is high in the western, northern, and central mandals of the basin.

Red Gram and Maize Region

4 mandals, namely Dhone, Bethamcherla, Veldurty, and Peapully, are noticed as the first-ranking crop regions, with the red gram crop in the study area. The maize region is a newly formed primary crop region during the period 2019–20, replacing Bengalgram, paddy, and red gram crops. The region has been found in three mandals, such as Nandikotukur, Pagidayala, and J.Bunglow, which are located in the north-eastern part of the basin.

Changes in First Ranking Crop Regions (2009-10 to 2019-20)

Significant changes have occurred in the primary crop regions of the basin over a period of ten years. In the year 2009–10, six primary crop regions were registered, namely groundnut, bengal gram, cotton, red gram, paddy, and fruits and vegetables. Even after ten years, groundnut, Bengal gram, cotton, and red gram remained as primary crop regions. However, the crop regions of paddy and fruits and vegetables disappeared in 2019–20. A new crop region, maize, was recorded during this period. Other changes include an increase in the number of mandals (administrative divisions) in the cotton crop region (+11 mandals) and red gram (+2 mandals). On the other hand, there was a decrease in the number of mandals in the groundnut (-9 mandals), Bengal gram (-5 mandals), paddy (-1 mandal), and fruit and vegetable (-1 mandal) crop regions. Additionally, a new region for maize emerged, consisting of 3 mandals that were previously part of the Bengal gram, paddy, and red gram crop regions. (**Fig.** 1 and **Table-**1).

Second Ranking Crop Regions or Second Order Crop Regions (2009-10)

The second ranking of crops comprises a greater number of crops compared to the first ranking of crops. In the year 2009–10, a total of 10 crops were classified as second-ranking crops. Among these, Castor held the highest position with 8 mandals of the basin. These are located in the north-western and southern parts of the basin. Next in importance among the second ranking of crops is groundnut. It is extended to only 6 mandals, namely Kodumur, C. Belagal,Bethamcherla,Adoni, Aspari, and Maddikera. Bengal gram is the third-important second-ranking crop cultivated in 5 mandals. They are J. Bunglow,Kowthalam, Nanavaram, Holagunda, and Pattikonda. The sunflower crop is the fourth important crop grown in 3 mandals located in the north-central part of the basin. They are in Kallur, Gudur, and Gonegandla.

Next in importance among the second ranking of crops are maize, fruits, and vegetables. The cultivation of maize is limited to 2 mandals, namely Nandikotukur and Pagidayala mandals. Similarly, the cultivation of fruits and vegetables is restricted to 2 mandals, namely Kurnool and Orvakal. Furthermore, there are several other crops, namely paddy, red gram, cotton, and tobacco, which are classified as the second ranking of crops in individual mandals. For instance, paddy is cultivated in Yemmiganur, red gram in Veldurthy, cotton in Alur, and tobacco in Miduthur mandals. (**Fig.** 2 and **Table-**2).

Second Ranking Crop Regions or Second Order Crop Regions (2019-20)

In the year 2019–20, there are five crops that contribute to the establishment of second-order crop regions. Groundnut, in particular, holds the most prominent position in the formation of these regions. As the second most significant crop, groundnut is cultivated in 9 mandals within the basin, specifically situated in the western and southern areas. Bengal Gram holds a significant position among the secondary category of crops, following closely after the primary ones. Its cultivation spans across 8 mandals. The distribution of Bengal gram is primarily concentrated in the northeastern region, with a few mandals also found in the southwestern part of the basin. The cultivation of cotton is the third most significant crop in terms of ranking, grown in 7 mandals. Additionally, paddy and fruit and vegetable crops are cultivated in 4 and 2 mandals, respectively.

Changes in Second Ranking Crop Regions (2009-10 to 2019-20)

In the years 2009–10, ten crops were reported as secondary crop regions, whereas in 2019–20, approximately five crops constituted secondary crop regions. An increase in the spatial distribution has been observed in cotton (+6 mandals), groundnut (+3 mandals), Bengal gram (+3 mandals), and paddy (+3 mandals). Conversely, a decrease in the number of mandals has been identified in castor (8 mandals), sunflower (3 mandals), maize (2 mandals), red gram (1 mandal), and tobacco (1 mandal). The fruit and vegetable crop region remained unchanged in terms of area, with 2 mandals in both 2009–10 and 2019–20.

Third Ranking Crop Regions or Third Order Crop Regions (2009-10)

Among the third-ranking crop regions of 2009–10, about 10 crops have been recorded in the basin (**Fig.** 3). Of these, Castor, Cotton, and Sunflower cultivation occupied first place in forming the largest third-order crop regions, as they comprised 5 mandals each, i.e., Castor in Gudur, Veldurthy, Pattikonda, Maddikera, and Gonegandla; Cotton in C. Belagal, Kosigi, Yemmiganur, Aspari, and Tuggali mandals; and Sunflower in Kurnool, Kodumur, Krishnagiri, Nandavaram,

and Alur mandal, followed by bengal gram (4 mandals); fruits and vegetables (3 mandals); red gram (2 mandals); maize (2 mandals); paddy (2 mandals); ground nut (1 mandal); and tobacco (1 mandal).

Third Ranking Crop Regions or Third Order Crop Regions (2019-20)

During the year 2019–20, eleven crops have been registered under tertiary crop regions with varied intensity. Fruits and Vegetables crop region emerged as the largest third ranking crop region with 9 mandals, followed by red gram (4 mandals), Bengal gram (3 mandals), paddy (3 mandals), groundnut (3 mandals), maize (2 mandals), condiments and Spices (2 mandals), cotton (1 mandal), jowar (1 mandal), minor millets (1 mandal), and chilies (1 mandal).

Changes in the Third Ranking Crop Regions (2009-10 to 2019-20)

Totally, about fourteen crops have been recorded in the study period under third ranking crop regions. They are castor, cotton, sunflower, Bengal gram, fruit and vegetables, red gram, maize, paddy, jowar, minor millets, chilies, condiments and spices, ground nuts, and tobacco. A decrease in the number of mandals under each third ranking region during the 10 years is observed in castor (-5 mandals), Cotton (-4 mandals), sunflower (-5 mandals), Bengal gram (-1 mandal), and Tobacco (-1 mandal). The increase in the number of mandals under each third ranking crop region during the 10 years of the study period is noticed in fruits and vegetables (+6 mandals), red gram, condiments and spices, and ground nuts (each with +2 mandals), paddy, jowar, minor millets, and chilies (+1 mandal). The maize region remained the same with two mandals, both in the 2009–10 and 2019–20 study periods.

Conclusion

During the years 2009–10, only six First Ranking crop regions, namely groundnut, Bengal gram, cotton, red gram, paddy, and fruits and vegetables, were noticed in the basin. Even after ten years, groundnut, Bengal gram, cotton, and red gram remained as First ranking crop regions. However, the crop regions of paddy and fruits and vegetables disappeared in 2019–20. A new crop region, maize, was recorded during this period. With regard to second ranking crop regions, ten crops were registered in 2009–10, and five crop regions, namely castor, sunflower, maize, red gram, and tobacco, disappeared in 2018–19, resulting in Five crop regions were recorded. About ten different third ranking crop regions have been reported in the year 2009–10 in the Tungabhadra River Basin, and eleven different third ranking crop regions have been noticed in the year 2019–20, with jower, minor millets, chilies, condiments and spices, and cotton as additional regions, replacing four crop regions of 2009–10, i.e., castor, Bengal gram, groundnut, and sunflower crop regions.

ANNUAL WATER BALANCE AND STREAM DISCHARGE MODELLING AT SHIMSHA WATERSHED OF UPPER CAUVERY BASIN, KARNATAKA

Dr. Surendra P. and Ms. Sneha Singh

Abstract

The present study mainly focuses on identifying the factors influencing water balance and stream discharge in Shimsha Watershed. The attempt also been made to analyse the water balance and stream discharge using SWAT model in the study area. Along with the use of SWAT model, geographical information system (GIS) is also used to estimate the HRUs, land use / land cover, calibrate and validate model and sensitivity analysis of SWAT model parameters for the Shimsha Watershed. The results show that Overall model performance was found to be agreeable as indicated by close relation between observed and simulated runoff. Model performance has been done using statistical parameter called Coefficient of Determination (R2). The R2 value were found to be 0. 64864 and 0.639706 after the calibration and validation. The model indicated very good agreement between simulated and observed flow. Therefore, it can be concluded that the SWAT model helps as an effective tool for assessment of water functioning at basin scale.

Introduction

Water is one of the most important natural resource. The Earth's water cycle is a dynamic and intricate system that plays a vital role in sustaining life and shaping our environment. Understanding the complex interactions of precipitation, evaporation, infiltration, runoff, and groundwater flow is crucial for effective water resource management, flood forecasting, and environmental protection. Hydrological models are useful tools that have been used in recent years to provide a visual representation of hydrological processes as well as accurate flow simulations, especially when evaluating the effects of land-use change and climate variability on hydrological cycles and water balance components. It encompasses a range of computational techniques that simulate the behaviour of water within a specific geographical area or watershed. By employing mathematical equations and algorithms, these models replicate the hydrological cycle, allowing us to observe and predict the movement

and distribution of water through the landscape. Hydrological models consider a multitude of factors, such as topography, land use, soil properties, vegetation cover, and climatic conditions, to create realistic representations of how water flows through a particular region. Water balance and stream discharge are important components of the hydrological cycle and are crucial for the management of water resources. Hydrological models provide a means to study the complex interactions between various hydrological processes in the Shimsha Watershed. While studying this we can analyse the relation between different parameters and how it is affecting the watershed Shimsha watershed covered with coconut plantation and medium dense urban settlement with using swat model what is the impact how the parameters are behaving within the watershed determined using the swat model. It is also important for the assessing water quality and pollutant transport within the watershed. Understanding the volume of water flowing through the stream helps in assessing pollutant loads and designing appropriate water quality management strategies in Shimsha watershed.

Study Region

The Shimsha River basin is a sub-basin of the Cauvery basin located in Karnataka, India. Geographically, it extends largely over two districts Mandya and Tumkur. The river has a course length of 221 km and has a catchment area of 8469 km^2 before joining the river Cauvery at shimshapura near the border of Chamarajanagara district. Shimsha river is an important tributary joining from left. The extent of area is latitude 13˚44′0″ N to 12˚8′0″N and Longitude 76˚8′0″ E to 77˚28′0″ E During the course of its travel from the origin many sub-tributaries join the Shimsha river such as Veeravaishnavi, Kanihalla, Chikkahole, Hebbahalla, Mullahalla and Kanva. At the mouth of the Shimsha river, a waterfall is situated at shimshapura in Malavalli taluk located 30 kms from Mandya, which was used to generate Hydroelectric power with an installed capacity of 17,200 kw and is considered to be the first ever hydroelectric project in Asia. The power generated during that time was used to light the Kolar gold fields. The Markonahalli dam, a multi-purpose reservoir has been erected across the river after it originates in Tiptur, Tumakuru district. It is reported to have been erected primarily as a flood-prevention measure for communities lying downstream, as well as to safeguard the safety of the nearby revered Yediyur Siddhalingeshwara Temple. Also, a barrage named after former Prime Minister H.D Devegowda has also been encountered during the course of its travel at Channapatna taluk, Ramanagara district – Igloor Dam Devegowda Barrage. The river then continues a southerly route and reaches

the Mandya district. The river travels in a south-eastern direction through Mandya district, with a waterfall at Shimshapura in Malavalli Taluk. Shimsha river is often referred as Madduru hole as the river passes through Maddur town and many villages of Maddur taluk. Shimsha is the principal irrigation supply for thousands of farmers in Nagamangala, Maddur, and Malavalli taluk, as well as hundreds of riparian villages in Tumakuru, Mandya, and Chamarajanagar taluks. The Shimsha Watershed is a geographical area in Karnataka, India, that is drained by the Shimsha River.

Objectives

(1) To analyses the water balance and stream discharge using SWAT model in study area.

(2) To identify the factors influencing water balance and stream discharge in study area.

Database and Methodology

In the present study following datasets were used to analysis the annual water balance and the stream discharge using SWAT model. Topography map was generated from the USGS-ASTER DEM with the spatial resolution of 30m. FAO – Digital soil map at the scale of 1:500000 used to create soil map. Land use and land cover map was derived from the ESRI Sentinel data with 10m spatial resolution. Followed by the rainfall data from IMD for the following years (1999-2022) and runoff (discharge) data from India water resources information system (WRIS) from 2001-2013 was used in this analysis. The following brief methodology was applied to assess the runoff and the water balance. The input data sets were derived from the above said data sources. Topography, soil texture, lulc, slope and rainfall layers were utilized as baseline parameters. From the DEM data watershed delineation and stream networks were generated. Followed by HRU analysis was carried with the support of DEM, Soil texture, lulc and slope along with rainfall in the SWAT model (SWAT RUN). Finally, surface runoff and the annual water balance were estimated for the Shimsha River basin.

Result and Discussion

SWAT Model Setup

The first step in model setup is to use a DEM raster file to delineate the watershed, sub- basins, and reaches. The definition of the watershed

gave a drainage pattern of land surface terrain, including the stream network and river basin outlets. The model used a DEM-based automated technique to delineate watershed. In which the watershed was divided into 7 sub watersheds, after providing a LU/LC map, soil map, and slope variation, they were further subdivided into 29 HRUs by the model (Hydrologic Response Units). HRUs, on the other hand, are combined units made up of homogeneous land-use and soil characteristics. A 10% threshold percentage has been implemented for all land use, soil, and slope classes in order to exclude minor land use, soil, and slope. The HRU report was then generated which included area of watershed (8694.15 km^2), detailed descriptions of the land use, soil, and slope classes in each sub- watershed.

Model Configuration

The SWAT model, is jointly developed by the United States Department of Agriculture – Agricultural Research Services (USDA–ARS), and Agricultural Experiment Station in Temple, Texas (Singh et al. 2013). By (Michael and Jain 2013), the computational components can be placed into eight major divisions namely: hydrology, weather, soil temperature, crop growth, sedimentation, pesticides, nutrients, and agricultural management, and uses physical inputs such as weather variables, topography, soil properties, land-management practices, and vegetation occurring in the catchment. SWAT explicitly models the physical processes related to water flow, sediment transport, crop growth, nutrient cycling etc. The form of water balance equation used to simulate the hydrologic cycle is depicted through equation.

(1) SWt = SWo + [Rday + Qsurf + Ea + Wseep + Qgw]

(2) SWt = Final soil water content in mm H2O,

(3) SWo = Initial soil water content in mm H2O, t time in days,

(4) Rday = Amount of precipitation on day i in mm H2O,

(5) Qsurf = Amount of surface runoff on day i in mm H2O,

(6) Ea = Amount of evapotranspiration on day i in mm H2O,

(7) Wseep = Amount of percolation and bypass exiting the soil profile bottom

(8) Qgw = Amount of return flow on day i in mm H2O

Watershed Delineation

Watershed is a hydrological unit from which runoff resulting from precipitation flows past a single point into a large stream, river, lake or pond. Watershed delineation

plays an important role in watershed management. Watershed delineation was performed in Arc GIS 10.4.1software. Digital Elevation Model (DEM) was use for watershed delineation. As top sheets provide information related to the location, drainage network and contours. Delineation of watershed has done using the dem, flow direction on map, flow accumulation on map, creation of outlet, snap pour point and watershed delineation.

SWAT Model Run

In this SWAT model to assess based on the Hydrological Response Units (HRUs) with the support of DEM (stream networks, watershed delineation, outlets for monitoring and sub basin parameter) and other thematic layers such as Land use land cover, soil, slope through overlay method. Include with this climatic dataset like rainfall and temperature which has been generated from the SWAT weather database (WGEN), followed by run the model to generate the runoff for the required number of years.

Hydrological Response Units (HRUs) Formation

The model simulates variations in evapotranspiration and other hydrological conditions for various land cover / crops and soils by subdividing the river basin into areas of exclusive land use and soil variations. The source of the hydrological modelling in SWAT is the HRU, which is a lumped land area within the sub-basin that is comprised of exclusive land cover, soil and slope. The sub-basin separation into HRUs improves precision and offers a much clearer physical description of the water balance. There are two options in SWAT for HRU allocation: either to assign a single HRU to each sub-basin or to assign multiple HRUs to each sub-basin (Srinivasan et al. 1998). If a single HRU per sub-basins is selected, the prevailing land use class and soil type surrounded by each river basin determines the HRU. If multiple HRUs are selected, the user must give a threshold level to ensure each grouping of land use and soil category within the sub-basin.

Sensitive Parameters

Sensitivity analysis can give a better understanding of the impact of change in an individual input parameter of the model response and can be performed using various methods. The method in the Arc SWAT interface combines the Latin Hypercube (LH) and One-factor-At-a-Time (OAT) sampling. Van Griensven et al. (2006), characterized Global rank 1 as “very important”, rank 2 to 6 as ‘important”,

rank 7 to 19 as "slightly important" and rank 28 as "not important". Sensitivity analysis was performed on 16 different SWAT model parameters for the Shimsha Watershed. Parameters and parameter ranges used in the sensitivity analysis. By using default upper and lower boundary parameter values, the parameters were tested for sensitivity using without observed streamflow data. The most sensitive factor governing the streamflow for the Shimsha Watershed was SCS runoff curve number for moisture condition II (CN2). This indicates that base flow is very significant in the water yield.

The Effective hydraulic conductivity in main channel alluvium (Ch_K2), threshold depth of water in the shallow aquifer required for return flow to occur (Gwqmn), available water capacity (Sol_Awc) and soil evaporation compensation factor (Esco) are also important parameters. Alpha_Bf and Sol_Awc were correlated to base flow and that could be the reason for their higher ranking in the sensitivity analysis. The sensitive parameters for the present study were selected based on the study conducted by Douglas – Mankin et al., (2010) on 64 selected watersheds. SWAT simulates the interaction of processes; many parameters affect more than one process. It's a kind of ripple effect. (For example, CN has direct impact on runoff; however, change in runoff changes other components of hydrology. There is direct impact of runoff change on soil erosion and nutrient transport affecting plant growth and nutrient cycling). So, Santhi et al., (2001) highlight this as the primary reason for manual calibration to start with hydrology balance and surface runoff, then sediment, and finally calibrating nutrients. From the above studies it was concluded to use the sensitive parameters such as CN2, ESCO, ALPHA_BF, SOL_AWC, SURLAG and RECH.DP and their initial and final values have been illustrated. The sensitive parameters are explained are as follows: Before calibration of CN2, ALPHA BF, GWQMN, ESCO, SOL AWC (84, 0.95, 0.8, 0.95, and 0.05) and after calibration of (35, 0.01, 0.05, 0.08, 1) respectively.

CN2

CN2 Initial SCS runoff curve number for moisture condition II. The SCS curve number is a function of the soil's permeability, land use and antecedent soil water conditions. The Soil Conservation Service Curve Number (SCS-CN) method is widely used in conceptual rainfall-runoff models for describing the runoff response with a curve, which is a function of the cumulative storm rainfall and antecedent wetness conditions. To improve the SCS- CN method.

ALPHA BF

ALPHA_BF Base flow alpha factor (1/days). The base flow recession constant, αgw, is a direct index of groundwater flow response to changes in recharge. Values vary from 0.1-0.3 for land with slow response to recharge to 0.9-1.0 for land with a rapid response. Base flow is the portion of streamflow that is delayed subsurface flow and generally maintained by groundwater discharge. Regardless of the specific climatic environment, its main features are tightly related to geological catchment properties. Base flow is the streamflow that constitutes the majority of the streamflow on a day when rain does not occur or has not occurred recently. Understanding the base flow process is important to deal with various water resources issues, such as water resources management strategies, low flow conditions assessment, hydrological modelling calibration, and water quality studies.

GWQMN

"GWQMN" stands for "Groundwater Quick Flow Manning's n" and it is a parameter used to represent the Manning's roughness coefficient for quick flow from the groundwater zone to the stream channel. In the SWAT model, accurate representation of groundwater dynamics and the interaction between groundwater and surface water is essential for realistic hydrological simulations. The GWQMN parameter contributes to this by influencing the rate of quick flow from the groundwater to the stream channel.

ESCO

ESCO stand for Soil evaporation compensation factor. This coefficient has been incorporated to allow the user to modify the depth distribution used to meet the soil evaporative demand to account for the effect of capillary action, crusting and cracks. ESCO must be between 0.01 and 1.0.

SOLAWC

It refers as the Soil Available Water Capacity parameter. This parameter is a key component of the model's representation of soil properties and their influence on water balance and hydrological processes within a watershed. Available Water Capacity (AWC) represents the amount of water that soil can hold and make available to plants for their growth and development. It is a crucial factor in determining how well a soil can retain and supply water to vegetation. The AWC parameter considers the soil's characteristics, such as texture, depth, and organic

matter content that influence its ability to retain water. Different soil types can have varying AWC values, and these values play a significant role in simulating various hydrological processes, including infiltration, runoff, evapotranspiration, and groundwater recharge. In SWAT, soil data are typically divided into different hydrologic response units, and each unit can contain multiple soil types. The "solawc" parameter is assigned to each soil type within an HRU, allowing the model to estimate how water moves through the soil layers, affects plant growth, and contributes to runoff and other hydrological responses.

Observed Discharge Data

The Runoff values for 18 years from 2004-2022 at the T.K Halli was simulated by the SWAT model and the comparison of output values with the observed data have been presented from which it can be seen that for most of the year, SWAT simulation seemed to overestimates the discharge when compared observed values. This is because of uncertainties in input data, model structure and model parameters. The calibration was carried out as a process of adjustment for these uncertainties. Due to continuous changes in the parameters the model simulated runoff and the observed discharge will correlate. The comparison between the observed and simulated discharge shows between 2004 to 2013. The Runoff values for 18 years from 2004-2022 at the T.K Halli was simulated by the SWAT model and the comparison of output values with the observed data have been presented from which it can be seen that for most of the year, SWAT simulation seemed to overestimates the discharge when compared observed values. This is because of uncertainties in input data, model structure and model parameters. The calibration was carried out as a process of adjustment for these uncertainties. Due to continuous changes in the parameters the model simulated runoff and the observed discharge will correlate. The comparison between the observed and simulated discharge shows between 2004 to 2013 (**Fig.** 1).

Surface Run-off Calibration

Most of the model inputs are physically based. The successful application of the model which are depends on how well the model is calibrated. The model will be calibrated using observed runoff data from the entire river basin. The calibration tool in the simulation menu of SWAT allows performing global changes on input parameters that are commonly modified during the calibration process. Calibration was performed manually from 2004 to 2005, and validation was performed from 2012 to 2013 run-off matches fairly well with observed runoff in trend and

magnitude. Overall, model performance was found to be agreeable as indicated by close relation between observed and simulated runoff. Due to changes in the sensitive parameters the model calibration done. The model efficiency checked using coefficient of determination or R square. This is a good method to signify the consistency among observed and good method to signify the consistency among observed and simulated data by following a best fit line. It ranges from zero to 1.0 with higher values indicating less error variance, and values greater than 0.50 are considered acceptable. In the calibration the R square was 0.64864 that's why this model is acceptable (**Fig.** 1).

Model Validation

Proper validation of the calibrated model is essential to understand its performance without any change in the input files except the climatic parameters. The monthly values of the maximum and minimum temperature for the time period for which the model is being validated is set as the input data for the model. The model was validated for similar parameters. Monthly run-off was compared for the river basin, as per the availability of observed data. In validation of the model the R square was 0.639706 which is acceptable. In the calibration and validation, the values of R square are more than 0.5 which is acceptable and is a good sign of model efficiency. So, the model is running properly and due to this model can run the future simulation also but in some points in graph the simulated and the peaks and are not matching is due to the uncertainty in the model's parameters and the input dataset. But the overall model is working properly and efficiently. The discharge is simulated in between 2020 to 2022. Due to the validation and calibration of model is running properly and can be used for future reference. This will help in future simulation as well managing the water movement in the study area will become very efficient. But there is still scope for future use ability of the model (**Fig.** 2).

Water Balance

This is the balance between the inputs and outputs of a drainage basin. Water balance is expressed as:

$$P = Q + E \text{ (+/- change in storage)}$$

Whereas:

P = precipitation Q = run-off

E = evapotranspiration

Fig. 2

Rivers will always have a regime which they follow, in that some months the discharge of the river will be higher than others. The water balance looks at how the amount of precipitation compares with the water leaving the system as runoff or as evapotranspiration. This balance will change throughout the year and will be affected by the overall climate of the area near to the river. For example, under 'usual' conditions the precipitation will be matched by run-off and evapotranspiration giving a 'normal' river level. If evapotranspiration becomes greater for a few months in summer while precipitation and run-off remain the same, the river will flow below normal level. Key terms to describe various water balance conditions are, namely, (1) Water Surplus: there is excess water available to the system. This occurs when precipitation exceeds evapotranspiration and the excess is not being used by plants (2) Deficiency: there is a reduction of water available within the system. This occurs when evapotranspiration exceeds precipitation (3) Recharge: after a period of deficiency precipitation will occur and replace the lost water in the soil. This needs to occur before a period of surplus can reoccur (4) Field Capacity: The maximum amount of water that soil can hold before it becomes saturated. A surplus can result in wet soils, high river levels and additional run-off whereas a deficit lead to dry soil, falling river levels and possibly a drier micro climate. The soil water content is around 4%, the surface runoff is 38%, percolation is 26% and the evapotranspiration is 32%.

The percolation of water is less in the Shimsha watershed; this study area is facing problem in the depletion of ground water. The main reason for this area is due to deep bore well digging which cause the problem in the area. It's necessary to understand the relation between the various water balance components. Using swat model, it is easy to understand how water is actually behaving in the study area and how the role of water is changing. In this study results shows that overall, model performance was found to be agreeable as indicated by close relation between observed and simulated runoff. The Calibration and validation were performed manually for the year 2004 to 2005 and 2012 to 2013 respectively on monthly basis. The Model performance has been done using statistical parameter called Coefficient of Determination (R2). Also shows that after calibration and validation R2 value were found to be 0.64864 and 0.639706 respectively. The model indicated very good agreement between simulated and observed flow. Therefore, it can be concluded that the SWAT model helps as an effective tool for assessment of water functioning at basin scale.

Conclusion

As the population growing impulsively, demanding urbanization, the expansion of industries and development in agricultural practices adds up to the increasing demanding for water and it is very much essential to manage the resource wisely. In the present study, to understand the status of water resources as well as hydrological process in the Shimsha river basin, SWAT model was applied. Since the river Shimsha waters vast areas of cultivation land our study at estimating the surface runoff at ungauged stations for effective watershed management practices. Calibration and validation were performed manually for the year 2004 to 2005 and 2012 to 2013 respectively on monthly basis. Model performance has been done using statistical parameter called Coefficient of Determination (R2). After calibration and validation R2 value were found to be 0. 64864 and 0.639706 respectively. The model indicated very good agreement between simulated and observed flow. Therefore, it can be concluded that the SWAT model helps as an effective tool for assessment of water functioning at basin scale. Under practical conditions it may be difficult to install discharge gauges everywhere along the stretch of stream, and may be in the future it is necessary to know the surface runoff at a required stretch where the discharge gauge station facility is not available or gives faulty measurements.

ETHICAL DIMENSIONS OF PROMOTING GIRL CHILD EDUCATION FOR SOCIAL EMPOWERMENT

Dr. Mohd Akhter Ali and M. Kamrajum

Abstract

This research paper explores the ethical considerations and societal implications of promoting girl child education as a means of social empowerment. It examines the intersecting factors of ethics, education, and society, focusing on the ethical challenges faced in ensuring equal access to education for girls and the transformative potential of education in fostering gender equality and social progress. The paper investigates the ethical dilemmas associated with gender disparities in education, the social barriers impeding girls' education, and the role of society in addressing these challenges. By analysing existing research and case studies, it aims to provide insights into the ethical dimensions of girl child education and its impact on the empowerment of girls and the broader society.

Introduction

Education is a fundamental human right that plays a pivotal role in individual empowerment and societal development. This is particularly true for girls, as girl child education has far-reaching implications for gender equality, poverty alleviation, and overall social progress. According to the United Nations (UN) Sustainable Development Goals (SDGs), ensuring inclusive and quality education for all, including girls, is a critical target to achieve by 2030 (UN, 2015). This brief overview will highlight the significance of girl child education, emphasizing the transformative power it holds for individuals and societies. Individual Empowerment. Access to education equips girls with knowledge, skills, and confidence, enabling them to make informed choices, fulfil their potential, and participate actively in society. Education empowers girls by broadening their horizons, expanding their opportunities, and breaking the cycle of poverty. Studies have shown that educated girls are more likely to marry later, have healthier families, and pursue higher education and career aspirations (UNESCO, 2018). Furthermore,

education empowers girls to exercise their rights, promotes critical thinking, and fosters leadership qualities, enabling them to contribute meaningfully to their communities and advocate for their own rights (Ghosh, 2016).

Societal Development

Investing in girl child education yields significant societal benefits and contributes to broader development goals. Educated girls become agents of change, driving social progress and economic growth. Research indicates that increasing girls' education results in reduced infant and maternal mortality rates, improved child nutrition, and healthier communities (Lloyd, 2016).. Moreover, educated women tend to have fewer children, which positively impacts population growth and allows for greater focus on quality education and healthcare for future generations (World Bank, 2018). Educated girls also have a higher likelihood of participating in decision-making processes, contributing diverse perspectives, and promoting gender equality in all spheres of society (UNESCO, 2020). Girl child education is of paramount importance for both individual empowerment and societal development. It not only empowers girls to break barriers and fulfil their potential but also yields far-reaching benefits for communities and nations as a whole. By investing in girl child education, we foster a more equitable and inclusive society, where girls can thrive and contribute meaningfully to the social, economic, and cultural fabric of their communities (Ali, M., & Kamraju, M. 2022. Gender disparities in education give rise to various ethical concerns that highlight the need for equal opportunities for girls.

These concerns revolve around principles of fairness, social justice, human rights, and the promotion of inclusive societies (UNESCO, 2017). Firstly, gender disparities in education violate the principles of equality and non-discrimination, as equal access to education is a fundamental human right (UNESCO, 2017). Denying girls, the same opportunities for learning and personal development that boys enjoy raises ethical concerns about fairness and equal treatment. Secondly, gender disparities in education perpetuate social injustices by reinforcing and perpetuating gender-based stereotypes and norms (Sen, 1999) . Such disparities limit girls' ability to realize their full potential, pursue their interests, and contribute meaningfully to society. Ensuring equal educational opportunities is a matter of social justice, aiming to rectify historical disadvantages and create a level playing field for girls. Moreover, education is a crucial tool for individual empowerment and agency. It equips individuals, including girls, with knowledge,

skills, and critical thinking abilities necessary for making informed choices and pursuing their aspirations (Nussbaum, 2000). Denying girls access to education denies them the opportunity to develop their potential, exercise their agency, and actively participate in shaping their lives and communities. In addition to ethical concerns related to individual empowerment, gender disparities in education hinder socioeconomic development at individual, community, and national levels. Education is strongly linked to economic growth, poverty reduction, and improved health outcomes (World Bank, 2018). By excluding girls from education, societies miss out on their potential contributions to economic productivity, innovation, and social progress. Addressing these ethical concerns requires concerted efforts from various stakeholders, including governments, policymakers, communities, and families. It involves implementing policies and interventions that promote gender equality, eliminate discriminatory practices, and ensure inclusive and quality education for all (UNESCO, 2017). By providing equal opportunities for girls to access education, societies can uphold ethical principles, promote social justice, and foster inclusive and equitable societies. Promoting girl child education. Promoting girl child education holds significant transformative potential and has far-reaching societal implications. By ensuring equal access to education for girls, societies can experience positive changes across various dimensions. Here is an overview of the societal implications and transformative potential of promoting girl child education:

(1) Gender Equality and Women's Empowerment: Girl child education is a critical step towards achieving gender equality. It enables girls to break free from traditional gender roles, challenge stereotypes, and pursue their aspirations. Educated girls are more likely to participate in decision-making processes, advocate for their rights, and contribute to policy discussions, leading to greater gender equality and women's empowerment within societies.

(2) Economic Development: Education plays a crucial role in driving economic growth and reducing poverty. Promoting girl child education leads to a more skilled and educated female workforce, enhancing productivity and innovation. Educated women can secure better employment opportunities, earn higher incomes, and contribute to the economic development of their families and communities. The World Bank estimates that investing in girls' education can lead to significant economic returns for societies.

(3) Health and Well-being: Educating girls has a positive impact on health outcomes for both individuals and communities. Educated girls are more likely to make informed decisions regarding their health, seek healthcare services, and adopt healthy behaviors. They are also better equipped to address maternal and child health issues, leading to improved healthcare practices and reduced mortality rates. Promoting girl child education contributes to better overall health and well-being outcomes for societies.

(4) Social and Political Participation: Education empowers girls to actively engage in society and participate in social and political processes. Educated girls develop critical thinking skills, become more aware of their rights, and are more likely to challenge social norms and discriminatory practices. Their participation in community development, civic activities, and political decision-making brings diverse perspectives and contributes to more inclusive and representative societies.

(5) Sustainable Development: Promoting girl child education aligns with the United Nations Sustainable Development Goals (SDGs), particularly SDG 4 (Quality Education) and SDG 5 (Gender Equality). Education is recognized as a catalyst for achieving multiple development goals. Educated girls become agents of change, promoting sustainable practices, addressing environmental challenges, and contributing to sustainable development in their communities.

By recognizing and investing in the transformative potential of girl child education, societies can break cycles of poverty, discrimination, and inequality. Empowered and educated girls become catalysts for positive change, creating more inclusive, equitable, and sustainable societies for present and future generations.

Ethical Considerations in Girl Child Education

Exploring the ethical dimensions of gender disparities in access to education sheds light on the underlying issues of discrimination, cultural biases, and social norms that hinder girls' educational opportunities. The following points delve into these ethical considerations:

(1) Discrimination: Gender disparities in education are rooted in discriminatory practices that systematically disadvantage girls. Denying girls equal access to education based solely on their gender violates principles of fairness, equality, and human rights. Such discrimination perpetuates social and economic inequalities and denies girls the opportunity to develop their potential.

(2) Cultural Biases: Cultural norms and beliefs can reinforce gender-based stereotypes, limiting girls' educational opportunities. Societies that assign traditional roles to girls often prioritize domestic responsibilities over education. Challenging cultural biases and norms requires careful navigation, considering the need to respect cultural diversity while ensuring equal educational opportunities for girls.

(3) Social Norms: Social norms shape attitudes and expectations surrounding girls' education. These norms can discourage families from investing in their daughters' education, perpetuating the cycle of gender disparities. Addressing the ethical dimensions of social norms entails challenging traditional perceptions of gender roles and promoting a shift towards valuing and prioritizing girls' education.

(4) Intersections of Discrimination: Gender disparities in education intersect with other forms of discrimination, such as those based on socioeconomic status, ethnicity, disability, or geographic location. These intersecting dimensions exacerbate the challenges faced by marginalized girls, compounding the ethical concerns surrounding their access to education. Efforts to address gender disparities in education should consider and address these intersecting forms of discrimination.

(5) Human Rights and Social Justice: Ensuring equal access to education for girls is not only a matter of human rights but also an ethical imperative rooted in principles of social justice. Every child has the right to education, regardless of their gender. Failing to address gender disparities in education perpetuates social inequalities and hinders societies from achieving inclusive and equitable development.

Recognizing and addressing these ethical dimensions requires a multifaceted approach. It involves promoting inclusive policies, challenging discriminatory practices, and fostering societal shifts towards gender equality and girls' empowerment. Ethical considerations in girl child education call for proactive measures to dismantle barriers, challenge biases, and ensure equal educational opportunities for all children, irrespective of their gender. Addressing gender disparities in education and ensuring equal educational opportunities for girls presents several ethical challenges. These challenges arise from complex social, cultural, and economic contexts and require thoughtful consideration and action. The following points discuss the ethical challenges associated with addressing these disparities:

(1) Cultural Sensitivity and Respect: Promoting girls' education while respecting cultural diversity can be a delicate balancing act. It requires acknowledging and appreciating diverse cultural norms and values while challenging discriminatory practices that hinder girls' education (Freeman, 2004) . Ethical challenges arise in navigating cultural sensitivity and ensuring that interventions do not inadvertently undermine cultural identities or perpetuate cultural imperialism.

(2) Overcoming Resistance and Changing Attitudes: Resistance to change and deeply ingrained attitudes and beliefs can pose significant ethical challenges. Challenging deeply rooted gender biases and stereotypes requires engaging with communities and addressing their concerns and misconceptions. Ethical considerations include promoting dialogue, fostering understanding, and building consensus to overcome resistance to girls' education (Sutton, 2011).

(3) Resource Allocation and Prioritization: Ethical dilemmas emerge when limited resources must be allocated among competing priorities. Governments and organizations face challenging decisions in distributing resources to address gender disparities in education. Balancing investments in girls' education with other pressing needs, such as infrastructure development or healthcare, requires ethical considerations in ensuring equitable resource allocation (Zaidi, 2012)..

(4) Sustainable and Context-Specific Interventions: Implementing sustainable interventions that address gender disparities in education necessitates understanding the specific contexts, needs, and aspirations of girls within different communities. Ethical challenges arise in developing interventions that are contextually relevant, sensitive to local dynamics, and responsive to the unique challenges faced by girls in various socio-cultural settings (Moosa, 2020) .

(5) Intersectionality and Inclusivity: Ethical considerations arise from the recognition that gender disparities intersect with other dimensions of identity, such as socioeconomic status, ethnicity, disability, or geographic location. Ensuring inclusivity and addressing the needs of marginalized girls requires an intersectional approach that acknowledges and responds to the unique challenges faced by different groups of girls (Crenshaw, 1989).

Addressing these ethical challenges requires a comprehensive approach that incorporates principles of justice, fairness, and respect for human rights. It involves engaging with communities, fostering dialogue, and tailoring interventions to specific contexts. Furthermore, addressing gender disparities in education should involve collaboration with diverse stakeholders, including governments, communities, civil society organizations, and international bodies, to collectively navigate the ethical challenges and work towards achieving equal educational opportunities for all children. Investing in girl child education carries significant ethical implications and has the potential for positive impacts on society. By understanding and addressing these ethical implications, societies can promote social justice, equality, and sustainable development. The following points examine the ethical implications of investing in girl child education and its potential positive impact on society:

(1) Ethical Imperative of Equal Opportunity: Investing in girl child education aligns with the ethical imperative of providing equal opportunities for all individuals. Education is a basic human right, and denying girls access to education is a violation of their rights to equality and non-discrimination (UNESCO, 2015) . By investing in girls' education, societies uphold principles of fairness, justice, and human rights.

(2) Empowerment and Agency: Education empowers girls, enabling them to exercise their agency, make informed decisions, and participate actively in society. Ethically, investing in girl child education acknowledges and supports the agency and autonomy of girls, enabling them to shape their lives and contribute to the betterment of society (Nussbaum, 2000) . Empowered girls become agents of change, promoting gender equality, social progress, and sustainable development.

(3) Breaking the Cycle of Poverty: Education is a powerful tool for breaking the cycle of intergenerational poverty. Investing in girl child education can lead to improved economic opportunities, higher incomes, and enhanced socioeconomic well-being for girls and their families (World Bank, 2018) . Ethically, by breaking the cycle of poverty, societies reduce inequalities and promote social inclusion.

(4) Health and Well-being: Education is closely linked to improved health outcomes for individuals and communities. Educated girls are more likely to make informed decisions regarding their health, adopt healthier behaviours, and contribute to healthier families and communities (UNESCO, 2017).

Ethically, investing in girl child education contributes to the promotion of health, well-being, and the fulfilment of individuals' right to health.

(5) Sustainable Development: Investing in girl child education is a strategic investment in sustainable development. Educated girls become agents of change, promoting sustainable practices, addressing environmental challenges, and contributing to the achievement of the United Nations Sustainable Development Goals (SDGs) (UNESCO, 2018) . Ethically, investing in girls' education acknowledges the interconnectedness of social, economic, and environmental well-being and the need for a holistic approach to development.

By recognizing the ethical implications and investing in girl child education, societies promote social justice, gender equality, and inclusive development. Empowering girls through education not only benefits individuals but also leads to positive societal transformations, fostering a more equitable, prosperous, and sustainable future.

Societal Barriers and their Ethical Implications

Societal barriers to girl child education pose significant ethical implications as they perpetuate inequality, restrict opportunities, and hinder social progress. These barriers arise from deep-rooted social norms, cultural practices, and systemic issues that must be addressed to ensure ethical and equitable access to education for all children. The following points examine some societal barriers and their ethical implications:

(1) Gender-Based Discrimination: Gender-based discrimination is a pervasive societal barrier that denies girls equal access to education. Discriminatory practices, such as early marriage, gender stereotypes, and biased cultural norms, limit girls' educational opportunities. Ethically, such discrimination violates principles of equality, fairness, and human rights, undermining girls' potential and perpetuating social inequalities.

(2) Child Marriage and Early Pregnancy: Child marriage and early pregnancy are significant barriers to girls' education. These practices not only deny girls the opportunity to complete their education but also expose them to health risks and limit their future prospects. Ethically, addressing child marriage and early pregnancy is crucial for protecting girls' rights, promoting their well-being, and ensuring their equal access to education.

(3) Socioeconomic Constraints: Socioeconomic barriers, including poverty, lack of financial resources, and economic inequalities, hinder girls' access to education. Ethically, it is imperative to address these constraints to ensure equal opportunities for all children, irrespective of their economic background. Tackling socioeconomic disparities requires targeted interventions, resource allocation, and equitable policies that prioritize education as a fundamental right.

(4) Cultural Norms and Stereotypes: Cultural norms and stereotypes often reinforce traditional gender roles and perpetuate biases against girls' education. Ethical considerations arise in challenging these norms while respecting cultural diversity. Balancing cultural sensitivity with the promotion of equal educational opportunities requires engaging with communities, fostering dialogue, and promoting awareness about the importance of girls' education.

(5) Lack of Infrastructure and Resources: Inadequate educational infrastructure, such as schools, classrooms, and sanitation facilities, can disproportionately affect girls' access to education. Limited availability of educational resources, including textbooks, teaching materials, and technology, further exacerbates disparities. Ethically, addressing these barriers requires investment in infrastructure development and resource allocation to ensure inclusive and quality education for all children.

(6) Gender-Based Violence and Safety Concerns: Gender-based violence and safety concerns in and around educational institutions create a hostile environment for girls, deterring them from attending school. Ethical implications arise in ensuring a safe and secure learning environment that protects the rights and well-being of girls. Combating gender-based violence and addressing safety concerns is essential to creating an ethical educational ecosystem (Pranathi, O., & Kamraju, M. 2023) .

Addressing these societal barriers requires collective action, involving governments, civil society organizations, communities, and individuals. Ethical considerations call for transformative measures that challenge discriminatory practices, promote gender equality, and uphold the principles of fairness, justice, and human rights. By removing these barriers, societies can create an inclusive and equitable education system that empowers girls, promotes social progress, and fosters a more just and sustainable future.

Role of Society in Promoting Girl Child Education

(1) Ethical Responsibilities of Stakeholders: Various stakeholders, including governments, policymakers, educational institutions, communities, and families, have ethical responsibilities in promoting girl child education. Governments and policymakers bear the responsibility of enacting and implementing policies that ensure equal access to education for all children, regardless of their gender (UNESCO, 2015) . Educational institutions should create inclusive environments free from discrimination, while communities and families must actively support and encourage girls' education, challenging harmful gender norms and stereotypes.

(2) Importance of Community Involvement: Community involvement plays a crucial role in promoting girl child education. Communities can create a supportive environment by recognizing and valuing the importance of girls' education. Engaging community leaders, parents, and local organizations in dialogue and decision-making processes helps address cultural barriers, dispel myths, and foster acceptance of girls' education (Gupta, 2013) . Ethically, community involvement ensures that interventions are contextually relevant, sustainable, and respectful of local customs.

(3) Awareness Campaigns and Advocacy: Raising awareness about the importance of girl child education is essential for creating a supportive environment. Awareness campaigns and advocacy efforts can challenge societal perceptions, highlight the benefits of educating girls, and mobilize public support (Ghosh, 2019) . Ethically, advocacy campaigns promote social justice and human rights by challenging discriminatory practices and influencing societal attitudes towards girls' education.

(4) Successful Initiatives and Interventions: Numerous successful initiatives and interventions have addressed ethical challenges and promoted girl child education. For example, the Kishoree Kontha program in Bangladesh focuses on empowering adolescent girls through education, life skills training, and community engagement (World Bank, 2020) . The Room to Read organization implements interventions that address cultural and economic barriers, providing girls with access to quality education in various countries (Room to Read, n.d.). These initiatives highlight the importance of context-specific approaches, community involvement, and multi-stakeholder partnerships in promoting girl child education ethically.

Integrating ethical considerations into interventions involves promoting social justice, equity, and human rights. It requires engaging with stakeholders, fostering dialogue, and ensuring the participation of marginalized communities. By recognizing and fulfilling their ethical responsibilities, stakeholders can collectively contribute to creating an enabling environment that supports and promotes girl child education.

Conclusion

In conclusion, the research highlights the ethical dimensions of promoting girl child education and the transformative potential it holds. It emphasizes the ethical responsibilities of various stakeholders, including governments, policymakers, educational institutions, communities, and families, in ensuring equal access to education for girls. The research underscores the importance of addressing societal barriers, such as discrimination, cultural biases, and social norms, which hinder girls' education and perpetuate inequality. Investing in girl child education is not only an ethical imperative but also a pathway to empowering girls and fostering social progress. Education equips girls with knowledge, skills, and agency, enabling them to overcome challenges, make informed decisions, and contribute positively to society. By providing equal educational opportunities, societies can promote social justice, gender equality, and sustainable development. However, there are ethical challenges associated with addressing gender disparities in education. These challenges include cultural sensitivity, overcoming resistance to change, resource allocation, developing context-specific interventions, and addressing intersectionality and inclusivity. Tackling these challenges requires collaborative efforts, dialogue, and transformative measures that uphold principles of fairness, justice, and human rights. Further research is needed to deepen our understanding of the ethical implications of promoting girl child education and to identify effective strategies to overcome barriers. Policy changes should prioritize girls' education, allocate resources equitably, and address systemic issues that perpetuate gender disparities. Collective action involving governments, communities, civil society organizations, and individuals is necessary to ensure equal access to education for all children, irrespective of their gender. In conclusion, promoting girl child education is not just an ethical imperative but also a means to create a more inclusive, equitable, and prosperous society. By recognizing and addressing the ethical challenges, we can unlock the full potential of girls, empower them as agents of change.

GEOPOLITICAL CONFLICT SITUATION AND PERSPECTIVE- A CASE STUDY OF INDIAN OCEAN

Dr. Navneet

Abstract

The geopolitics of the Indian Ocean region holds paramount significance in the contemporary global landscape. This paper delves into the multifaceted dimensions of Indian Ocean geopolitics, encompassing historical, economic, environmental, and strategic considerations. Employing a comprehensive methodology that incorporates geopolitical databases, economic and trade statistics, environmental data, and historical archives, the study aims to unravel the intricate interplay of actors, interests, and power dynamics in the region. The Indian Ocean, boasting critical choke points like the Strait of Hormuz and Bab-al-Mandeb, serves as a nexus for international trade and political activities. As the repository of a substantial share of the world's oil, gas, uranium, gold, and diamond reserves, the Indian Ocean region emerges as a focal point for global economic dynamics. Furthermore, it houses vital minerals, amplifying its strategic importance. The region's geopolitical landscape is marked by the presence of diverse littoral states, each with its unique historical trajectory, economic aspirations, and security concerns.

Introduction

Geopolitical analysis often examines the Earth's composition of land and water, a concept with a long history spanning hundreds of years. This perspective considers the interconnectedness of humanity, states, and the environment. The Earth can be categorized into hemispheres based on water and land distribution. The rise of globalization has amplified the importance of the Indian Ocean in economic affairs. In terms of size, the Indian Ocean ranks third globally, holding approximately 20% of the world's water. Analyzing the world map through Mercator's projection provides insight into the geopolitical importance of the Indian Ocean, which extends from 20 degrees E to 120 degrees E longitude. Notably, all nations along the Indian Ocean coastline, excluding Australia and South Africa, fall within the underdeveloped or developing categories. Furthermore, the majority of these nations comprise a significant portion of the Third World, sharing common

characteristics, notably having been part of colonial empires of Western European nations until gaining independence, primarily between the 1940s and 1960s. With limited exceptions, these nations were integral components of the colonial empires of Western European nations for substantial durations throughout the 19th and 20th centuries. They achieved liberation, whether through peaceful methods or other means, from colonial dominion between the 1940s and 1960s.

Study Region

This article is study of Indian Ocean region. The emerging nation-states facing heightened vulnerabilities and instabilities due to their underdeveloped status. Their ambitions and frustrations stem from the allure of development benefits on one hand and the constraints of economic backwardness on the other. These nations collectively grapple with the challenges and disruptions associated with the shift from traditional cultural values to those required by industrial economies in the nuclear age. Access to the ocean can be gained through either two narrow northern "choke-points" – the Suez Canal/Horn of Africa and Singapore/Straits of Malacca – or two southern border "gateways" at the southern extremities of Africa and Australia. The southern Indian Ocean, in reality, provides the most direct route between the Pacific and Atlantic Oceans. Moving beyond the coastal states, the northern landmass is primarily shaped by the influence of the Soviet Union and China, both Communist powers in ideological conflict with the Western world. Specifically, the Soviet Union, as a superpower, has been in a conflict with the United States, the other superpower. Strategically, the Indian Ocean region represents a vulnerable aspect for the Soviet Union, with limitations in reducing its vulnerabilities. Following the British announcement in 1968 regarding their withdrawal from the Indian Ocean Region by 1971, the two superpowers – the United States and the Soviet Union – became deeply involved. The subsequent two decades witnessed an escalation in militarization and superpower rivalry. The economic and political aspects of the Indian Ocean have seen growth alongside the expansion of globalization.

Objectives

(1) The significance of Indian ocean in geopolitics of region

(2) How is Indian Ocean strategically important for India?

(3) Why United States is interested in Indian Ocean region?

(4) Why china wants its domination in Indian Ocean?

Database and methodology

This article used primary and secondary data. Articles, books, newspaper, government documents, reports. Utilize geopolitical databases that compile information on international relations, conflicts, and geopolitical events. Access databases that provide economic and trade statistics for countries in the Indian Ocean region. International organizations like the World Bank and the International Monetary Fund (IMF) offer comprehensive datasets. Explore historical archives and libraries for primary sources that offer insights into historical geopolitical events in the Indian Ocean region. The methodology used in article is qualitative. Analysis of indian ocean rgionis conducted to know its significance. Conduct a thorough literature review to understand existing theories, frameworks, and scholarly work on Indian Ocean geopolitics. Identify gaps or areas for further exploration. Analyze specific case studies within the Indian Ocean region to gain a nuanced understanding of geopolitical dynamics. Focus on historical events, conflicts, or cooperative efforts. Explore different scenarios and potential future developments in the region based on geopolitical, economic, and environmental factors.

Results and Discussion

Initially, the United States demonstrated a lack of interest in filling the gap left by Britain's withdrawal from the Suez Canal. However, developments in the 1970s and 1980s compelled the U.S. to become involved in the Indian Ocean region. The U.S. strategically nurtured relations with China, capitalizing on the rivalry between China and the Soviet Union. Simultaneously, the U.S. refrained from intervening in South East Asia to allow China to reap the benefits. The U.S. directed its efforts toward maintaining influence in South Asia, West Asia, and Southwest Asia for its own strategic advantage. In contrast, the Soviets adopted a policy of supporting anti-imperialist forces and advocating for the independence of nations in former colonies. The shared anti-imperialist sentiment served as a basis for cooperation among states aspiring for socio-economic improvement in partnership with the Soviet Union. The Soviet Union aimed to diminish the influence of the United States in newly independent and developing countries, particularly given the growing collaboration between the U.S. and China. The Indian Ocean holds significance for trade and commerce, serving as a crucial link between the East and West. The political importance of the Indian Ocean has grown due to the ideological conflict between the two superpowers. According to the United States, the Indian Ocean is pivotal to its strategy of fostering positive relations and exerting influence in newly independent states. Conversely, the USSR views the U.S. strategy as a potential

threat to the sovereignty of these newly independent states and a hindrance to its own security. The geostrategic relevance of the Indian Ocean is heightened by its access to sensitive global areas and key choke points, such as the Malacca Strait.

Strategic Significance of Ports

China and India are making substantial investments in the development of seaports in the Indian Ocean, recognizing its strategic significance. India is actively involved in the construction of the Chabahar port in Iran, aiming to secure access to landlocked Central Asian countries. In response, China is building the Gwadar port in Pakistan, directly challenging India's interests. The presence of an anti-Sunni regime in Iran introduces vulnerabilities in the operational efficiency of the Chabahar port, posing challenges to India's maritime interests. In 2008, the Chief of the Indian Navy highlighted the strategic implications of the Gwadar port, emphasizing its potential to empower Pakistan in controlling strategically important energy sea lanes in the Persian Gulf. The growing geopolitical importance and cohesion of the Indian Ocean region are substantiated by at least three factors: the proliferation of regional strategic connections, the Indian Ocean policies pursued by external powers, and the collective indigenous responses to external intervention. The proliferation of regional strategic linkages underscores the increasing interconnectedness of events in the Indian Ocean area.

These events may be linked in two primary ways. Firstly, through a "linkage of instabilities," wherein the instabilities and imbalances in one sub-region not only affect neighboring countries but can also extend into more distant parts of the region, forming a comprehensive "linkage of instabilities" throughout the area. The impact of a situation may vary based on its occurrence, with implications differing for events near and further away. For instance, the Vietnamese invasion of Kampuchea has led to a significant refugee crisis and concerns about a direct security threat in Thailand, while in Indonesia and Australia, it is perceived as an unwelcome and perilous manifestation of regional instability. Similarly, the Soviet invasion of Afghanistan raised fears of a direct Soviet threat to Pakistan and Persian Gulf oilfields, causing apprehension in distant parts of the region about the means and objectives of Soviet policy. Consequently, due to such developments over the past decade, it is now improbable that any event impacting the security of even the smallest state in the Indian Ocean region will be dismissed as inconsequential to the other states in the area. Subsequently, interconnections arise among sub-regions when individual states or groups of states deliberately implement security policies on a scale beyond their immediate sub-regional context.

An example is the collaborative efforts of black states in southern Africa, in conjunction with other African nations, actively working to isolate and apply pressure on white-ruled South Africa. Similarly, there is widespread support from the nations along the Indian Ocean coast for the proposal to designate the area as a zone of peace. Another illustration is Saudi Arabia's policy, which seeks to integrate security postures from the Red Sea area through the Gulf to the extremities of the Indian subcontinent. Presently, the process of linkage seems fragmented, with states in one subregion generally not seeking security alliances with those in another. Security linkages have primarily been extra regional, involving a local state and an external power, such as Australia with the United States, India with the Soviet Union, and Pakistan with China and the United States. Although limited, the success of formal alliances between states of different subregions, as seen in SEATO (South-East Asia Treaty Organization) and CENTO (Central Treaty Organization), suggests the potential for more formal sub-regional coalitions in the future. Additionally, the Gulf Cooperation Council is progressing towards forming a security alliance, as previously mentioned.

The strategies of the two superpowers hold paramount significance. Their immediate concerns in the region have intertwined with the broader dynamics of their global competition, making the Indian Ocean a strategically vital arena for both. In contrast to Japan and Western Europe, which relied on Gulf oil for approximately 90% and 75% of their respective needs during the 1973-1974 embargo, the United States did not have a comparable dependence on Gulf oil. The significant outcome of the embargo wasn't just the impact on Western economies but the intense discord and internal conflicts within the Atlantic alliance. Member states and Japan engaged in fierce competition for privileged access to unembargoed oil and future access to Arab oil. The United States is eager to avoid a prolonged denial of Persian Gulf oil to the West, not only for economic reasons but also to maintain alliance solidarity. Despite the current surplus in global oil supplies and declining prices, Persian Gulf oil, constituting about 55% of the world's proven reserves, will remain strategically crucial for the West until the end of the century. In the past, the United States leaned on local allies to protect its fundamental political, economic, and strategic concerns in the Indian Ocean region. Yet, a shift occurred in the late 1970s, with the U.S. adopting a new strategy for its security interests in the area. This approach actively aimed to enhance access to naval, air, and communications facilities across the region. It involved improving the operational capabilities of the British-owned Diego Garcia, increasing naval deployments in the Indian Ocean,

and establishing the Rapid Deployment Force. These initiatives significantly strengthened the U.S.'s capacity to exert influence in the Indian Ocean, indicating a commitment to a more engaged role in the region. While the focus of these efforts might appear centered on the Persian Gulf, it is crucial not to characterize the policy as exclusively Gulf-centered. Although additional forces and facility improvements suggest a concentrated approach, U.S. military resources are limited and must be allocated based on strategic priorities. The emphasis on the north-west quadrant of the Indian Ocean highlights the importance Washington attributes to its Gulf interests and an overarching concern for the stability of that subregion. However, the U.S. has not neglected its military and political interests in other parts of the region, as evidenced by recent endeavors to strengthen military capabilities in the eastern approaches to the Indian Ocean, including securing landing rights for B-52 bombers in Australia

Non State Actors and their Threat

Non-traditional threats to global security have experienced significant growth, and India is grappling with major challenges such as maritime terrorism, gun-running, drug trafficking, and piracy along its sea borders. Given the crucial shipping lanes traversing the region, India has been underscoring the significance of maritime security in the Persian Gulf and the Gulf of Aden. Various terrorist organizations, including Al Qaeda, utilize maritime routes around India in the Indian Ocean region for narcotics and arms trafficking, financing their operations. Indian intelligence agencies have cautioned the government about potential seaborne attacks by terrorist groups targeting the nation's oil rigs, encompassing production and support platforms along both coasts. Piracy poses a significant threat in various parts of the Indian Ocean, notably the Malacca Straits and the Horn of Africa, necessitating a robust Indian maritime presence. Reflecting this perspective, the Indian maritime doctrine asserts that the arc from the Persian Gulf to the Straits of Malacca is a legitimate area of interest for India in the twenty-first century. The majority of attacks and hijackings on the high seas concentrate in three key areas: the Gulf of Aden and the eastern coast of Somalia, the coast of West Africa (particularly off Nigeria), and the Indonesian archipelago. In the initial quarter of 2008, over half of all attacks occurred in the Gulf of Aden. In 2008, a significant surge in piracy incidents took place, with at least 92 ships attacked in and around the Gulf of Aden, surpassing the number in 2007. An estimated $25 to $30 million was paid in ransom to Somali pirates. Responding to heightened concerns,

particularly after the hijacking of the merchant vessel MT Stolt Valor off the coast of Somalia in September 2008, the Indian government authorized the Indian navy to initiate patrols in the Gulf of Aden and provide escorts to Indian merchant vessels. India holds an economic stake in safeguarding not only Indian-owned but also non-Indian-owned cargo ships in the Gulf of Aden shipping lanes. Approximately 85 percent of India's sea trade on this route is transported by foreign-owned ships, and about one-third of India's entire fleet of 900 cargo ships operating in international waters is vulnerable to risks. The patrolling conducted by the Indian navy aims to secure the nation's sea-borne trade, instill confidence in the maritime community, and serve as a deterrent to pirate activities. While Russia, NATO, and EU forces have initiated patrols in the region, coordination efforts remain disjointed. India argues for the establishment of a peacekeeping force under a unified command to ensure security in pirate-infested regions for international shipping.

In a noteworthy operation—the first of its kind since the 1971 war with Pakistan—India's stealth frigate, INS Tabar, engaged and sank a pirate "mother vessel" in the Gulf of Aden, later revealed to be a Thai trawler. The Indian naval vessel fired in self-defense as the trawler, commanded by pirates who refused to surrender, posed a threat. This incident underscored the Indian navy's capabilities on the high seas, previously demonstrated during tsunami relief operations and the evacuation of Indian nationals in the Lebanon War of July-August 2006. The Indian navy showcased its autonomy and proficiency in serving a collective good: the protection of global maritime trade. India utilized this demonstration to project itself as a nation capable of safeguarding its maritime interests and commercial sea routes in international waters. While this highlighted the Indian navy's prowess on the high seas, questions were raised about its ability to counter terrorism on the home front, especially following a severe assault on Mumbai in November 2008, where terrorists managed to outwit the Indian navy and Coast Guard.

The terrorists successfully infiltrated Mumbai using a trawler, revealing a systemic failure within Indian security agencies. India's Coast Guard is responsible for securing the Exclusive Economic Zone within 200 nautical miles, while the navy oversees the blue water beyond. Despite the clear recognition of the threat of terror attacks from the sea, no measures were taken to reinforce anti-terror defenses. India's extensive coastline, coupled with insufficient policing, facilitates the clandestine landing of arms and explosives at isolated coastal points. This method was exploited in 1993 for the bomb blasts in Mumbai, and it was employed again in the 2008 terrorist attacks. The Indian Naval Chief took

responsibility for the lapse, citing weak infrastructure for patrolling and surveilling coastal areas. Despite actionable intelligence, both the Coast Guard and the navy failed to detect or intercept the Pakistani ship transporting terrorists from an Indus creek near Karachi, Pakistan. The escalating global threats from non-state actors necessitate India's collaboration with other major naval powers, not only to address issues like piracy but also to tackle broader security concerns for maritime commerce. Given the Indian navy's demonstrated effectiveness in providing the government with operational leverage in the Indian Ocean, its role in projecting power and safeguarding national interests is expected to grow. However, a significant challenge to the Indian navy may emerge from the expanding influence of another major Asian power in the Indian Ocean i.e. China.

In 2006, China surpassed Japan as the largest military spender in the Asia-Pacific, now holding the fourth-largest defense expenditure globally. While there is contention over the exact figures, with estimates ranging from China's official claim of $35 billion to the US Defense Intelligence Agency's estimate of $80-115 billion, the clear trend is a significant increase in Chinese military spending, showing a 195 percent rise from 1997 to 2006. The official Chinese figures do not encompass costs for new weapons purchases, research, or other major items for its secretive military. Calls for transparency in China's military intentions and capabilities have arisen globally, from Washington to Tokyo, Brussels, and Canberra. According to the 2006 Defense White Paper, China's navy aims to gradually expand its strategic depth for offshore defensive operations, enhance capabilities in integrated maritime operations, and develop nuclear counter-attacks. The Chinese navy now ranks as the third-largest globally, surpassing the Indian navy both qualitatively and quantitatively.

Historically a coastal force with a continental security outlook, China's economic rise since the 1980s has led to a maritime orientation with intentions to project power into the Indian Ocean. China is investing significantly more in modernizing its armed forces, particularly its navy, than India currently appears willing or able to sustain. China's growing submarine fleet, including sophisticated submarines, ballistic missiles, and GPS-blocking technology, positions it to potentially challenge the United States. There are indications that China plans to build an aircraft carrier by the end of the decade, a departure from its earlier focus on Taiwan. As China's economic and political influence expands, its profile in the Indian Ocean region has grown, with efforts to acquire naval bases along crucial chokepoints for economic and strategic purposes. China's comprehensive development of maritime power reflects

its ambition to dominate the strategic maritime space in the Indian Ocean region. To overcome the geographical distance, China relies on bases in the littoral regions of the Indian Ocean. The "String of Pearls" strategy exemplifies China's increasing naval power and encircling approach, particularly evident in its efforts to dominate the South China Sea and deploy submarines near the Strait of Malacca, a vital entry point to the Indian Ocean. Despite India's geographical advantage, China's expanding naval capabilities pose a strategic challenge for India in the region. China is actively pursuing the development of its maritime economy and aims to establish the world's largest merchant fleet, backed by extensive port and shipbuilding infrastructure. While China-India relations have been steadily improving since the 1990s, there has consistently been an underlying sense of competition. China has effectively cultivated strong ties with Pakistan through its economic and military influence. Although China aspires to dominate the Indian Ocean and achieve naval supremacy, this goal remains a distant prospect.

Indian Response to China in Indian Ocean

Strategic Partnerships: India has fostered strategic partnerships with countries in the Indian Ocean region to counterbalance China's influence. Bilateral and multilateral engagements with nations like the United States, Japan, Australia, and those in Southeast Asia have become more pronounced. Naval Modernization: India has been investing in the modernization of its naval capabilities to enhance maritime security. This includes the development of a robust naval fleet, acquisition of maritime surveillance systems, and the establishment of coastal surveillance networks. Infrastructure Development: India has been working on enhancing its maritime infrastructure, including port facilities, to strengthen its presence in the Indian Ocean. Projects such as the development of the Chabahar Port in Iran aim to provide India with strategic access to Central Asia. Diplomacy and Regional Cooperation: India has engaged in diplomatic efforts and regional cooperation to address common security concerns. Initiatives like the Indian Ocean Naval Symposium (IONS) and the Indian Ocean Rim Association (IORA) have been platforms for dialogue and collaboration. Focus on Maritime Domain Awareness (MDA): India has increased its focus on MDA to monitor and respond to maritime security threats effectively. This involves intelligence-sharing agreements, joint patrolling, and coordinated efforts with partner nations. Anti-Piracy Operations: India has actively participated in anti-piracy operations in the Gulf of Aden. The Indian Navy has deployed warships to ensure safe passage for merchant vessels and counteract piracy in the region. It's important to note that the geopolitical

landscape is dynamic, and developments may have occurred since my last update in January 2022. For the latest and more detailed information, please refer to recent academic publications, official government statements, or reputable news sources.

Conclusion

The Indian Ocean has evolved into a focal point for global economic and political endeavors, attaining strategic significance due to key chokepoints like the Strait of Hormuz and Bab-al-Mandeb. There exists a need for a renewed geopolitical framework for the Indian Ocean region, departing from traditional military-centric perspectives, and challenging the imperialist history of international maritime relations. The notion of 'mastery' or 'conquest' of the oceans must be reevaluated, recognizing the finite capacity of the marine environment and prompting exploration of new perspectives. Establishing a peaceful, socially equitable, gender-sensitive, and environmentally sustainable 'order' for the oceans requires patient negotiations and consensus-building, steering away from exclusively state-led management or region-specific development approaches. The Indian Ocean region and its coastal areas harbor over two-thirds of the world's oil reserves, 35% of global gas reserves, and significant proportions of uranium (60%), gold (40%), and diamond reserves (80%). Moreover, the region's importance is underscored by its mineral wealth, encompassing reserves of beryllium, coal, copper, iron, tin, chromite, manganese phosphate, and lithium. Positioned strategically, the Indian Ocean holds a unique geopolitical status, being the only ocean named after a country.

STUDY OF LITERACY GAP AMONG GENDER: A BLOCK LEVEL ANALYSIS OF LUCKNOW DISTRICT

Shashank Tripathi and Dr. Rana Pratap Yadav

Abstract

Literacy is the ability to identify, understand, interpret, create, communicate and compute, using printed and written materials associated with varying contexts. Literacy is considered an important key to social-economic progress. Literacy & education attainment are important indicators of the development of a society. It helps in eliminating gender disparity at all level. In India the reality of gender inequality is very complex and diversified because it exists in various fields like literacy, health, employment etc. According to the Census of India 2011, the overall literacy rate of India is 74% with male literacy being 82% & female literacy at 65%. A sizeable gender difference of 17% can be observed in the literacy rate. Such disparities between male and female literacy can be seen at both state and national levels. Recent decades manifest growth in literacy but the gap still exists and is predominant in rural areas. Lucknow district also witnesses gender disparity in literacy. The present study is an attempt to evaluate literacy gap among gender & its regional variations in the administrative blocks at the district level. This paper provides an insight into the Spatio-temporal patterns of male-female literacy & its level of disparity. This study is based on secondary sources of data collected from the District Census Handbook. The method adopted in the study to calculate the disparity in literacy is Sopher's Disparity Index (1974). Between the years 2001 and 2011, the study area has seen a fall in the gender gap and an increase in the male-female literacy rate. The gender literacy gap has been bridged largely due to initiatives like Beti Bachao, Beti Padhao, and the National Program of Education for Girls at the Elementary Level (NPGEL). But still, there is a scope for improvement in women's literacy levels for this the research will be useful in suggesting some relevant strategies and policies with implications for reducing gender inequality and promoting the dignified position of women.

Introduction

Literacy is a crucial indicator of the social and economic development of a nation. It plays a significant role in removing inequality along with the development of society and its individuals. It is the fundamental building block for a country's development. Literacy is a highly important tool for people to learn and develop skills that will enable them to understand and have a positive attitude for society. It also helps in analyzing the inequalities and factors responsible for poverty and exploitation in the society. Kofi Annan, Former Secretary General of the United Nations had quoted, "Literacy is a bridge from misery to hope. It is a tool for daily life in modern society. It is a bulwark against poverty and building blocks of development, an essential component to investments in roads, dams, clinics & factories. It is a platform for democratization & a vehicle for promotion of cultural & natural identity. It is the way to human progress & the means through which every man; woman & child can realize his or her full potential". The definition of literacy given by UNESCO (1957), "A person is literate who can with understanding both read and write a short simple statement on his/her everyday life". In simple words according to UNESCO it means "Literacy is the ability to identify, understand, interpret, create, compute & use printed & written material associated with varying contracts". According to Census of India 2011, "Any person (aged 7 & above) is considered a literate, if he or she can read & write in any language with complete understanding". Researchers, Academicians & policy makers have rated literacy as the starting point of development (Pattinson1982, Strect 1984).

Literacy unlocks the door to learning throughout life is essential, is essential to development & health & opens the way for democratic participation & active citizenship (Kofi Annan, Former Secretary General of the United Nations). Literacy influences & determines qualitatively & quantitatively not only human resources but also other demographic attributes like fertility, mortality, and economic participation of women &age of marriage ultimately aiming towards welfare of the society (Sawant & Lewis, 2004). Literacy is both the cause & result of development (Mohapatra,1993). Literacy is tool to empower women in the wider struggle against inequality & injustice in society (Patel & Dighe,1997). Higher levels of literacy are a good predictor of both a growing economy and a high standard of living. According to the Census of India 2011, the overall literacy rate of India is 74% with male literacy being 82% & female literacy at 65%. Uttar Pradesh recorded as a whole 77.3% of males & 57.2% of female literates. Lucknow district as a whole accounted for 82.6% of male & 71.5% of female literates respectively. At the national, state,

district, and block levels, disparities between males and girls in literacy can be observed. Recent decades have witnessed growth in literacy rate but the disparity in literacy still exists and can be predominantly seen in rural areas of the country. This is generally because the rural areas are dominated by agricultural activities while the urban regions are driven by the tertiary sector. Thus, a difference in economy, infrastructural facilities, accessibility, the standard of living, and women status can be observed. Differences in literacy are important for a variety of reasons. Due to the underutilization of potential human capital, a biased allocation of educational resources implies significant costs for social welfare. Some important factors like-poverty, early marriage, dowry, preference for boy's education, lower enrollment, etc are responsible for creating such disparities in literacy. Grover R.P., & Bhardwaj, R., (2002) have rightly pointed out that administrators & planners must pay greater attention in bridging the gap between literacy of males & females. As literacy is related to both social needs and economic development, there is a need to implement integrated literacy programs for rural development, with a particular focus on skill development and income generation programmes. A woman holds a pivot position & plays multiple roles in the development of modern society. It is widely argued, "When you educate a man, you educate a person; but when you educate a woman, you educate a generation." The Sustainable Development Goal (SDG) 4 also talks about ensuring inclusive & equitable quality education & promote lifelong learning opportunities for all. It will confront a holistic approach to educating people & boosting literacy levels to meet sustainable development goals that have yet to be made by 2030.

Study Region

Lucknow is the capital city of Uttar Pradesh which is located on the banks of river Gomti dividing the whole city diagonally into cis-gomti & trans-gomti regions . The total area of the district is 2528sq km. It exists between 26°30' to 27°10' North latitude and 80°34' to 81°12' East longitude. The district is surrounded in the northern side by district Sitapur, on the southern side by district Raebareli, on the eastern side by Barabanki district, on the south-western side by Unnao district & on the north-western side by Hardoi. The administrative setup of the district is divided into 4 tahsils & 8 development blocks namely Mal, Malihabad, Bakshi Ka Talab, Chinhat, Kakori, Sarojaninagar, Gosainganj & Mohanlalganj. There are total of 12 towns (10 statutory towns & 2 census towns. The adjoining districts are dependent on Lucknow district & mostly the Lucknow city for better education & health facilities & various job opportunities.

Objectives

(1) To find out the gender disparity in literacy rate.

(2) To suggest suitable measures for reducing disparities in literacy rate.

Database and Methodology

The present study is based on secondary data & sources obtained mainly from the Census of India, relevant issues, 2001 & 2011 & District Census Handbook of Lucknow-2001 & 2011. The block-wise data of the literate population & literacy rate for the 2001 and 2011 censuses are available. The tabulation and graphical representation of the data are done and represented through maps. The methodology adopted to measure gender disparity is Sopher's Disparity (1972). It is calculated using the following expression:

$$DI = \text{Log } X2/X1 + \text{Log } 100\text{-}X1/100\text{-}X2$$

Whereas: $X2 \geq X1$

DI- Disparity Index

X2- Percentage of Male Literates

X1- Percentage of Female Literates

Q- 100

To measure gender disparity in literacy, male literacy is taken as X2 & female literacy as X1, Where X2 is generally more than that X1. The Log value is taken to reduce the leveling-off effect (Sopher 1972). The value should range between +1 & -1. In the case of perfect equality, no disparity exists between the two variables. If the value is greater, it represents high disparity and if the value turns out to be lesser it shows low disparity. It is generally used in measuring the relative disparity. The study of the disparity index of literacy is grouped into 3 categories, namely, Low Disparity, Medium Disparity and High Disparity.

Results and Discussion

Being a universal phenomenon, the disparity in male-female literacy varies from region to region. The study area is also not free from this disparity. According to Census 2001, the total literacy rate of Lucknow district was 68.25% with male & female literacy rates being 75.98% & 60.47% respectively. With the passage of time, the study area witnessed a significant jump in total literacy by 77.3% with 82.6% as male literates & 71.5% as female literates in the 2011 Census (**Fig.** 1.)

Though, the disparity got narrowed down from the 2001 to 2011 census but, still, a large number of people are illiterates existing in the study region & acting as a major obstacle in the socio-economic development of the area. The present paper is an attempt to study regional variation of gender disparity in literacy in the study area by using Sopher's Disparity Index. This disparity is calculated for all the administrative blocks for the censuses 2001 & 2011. On the basis of values of literacy, the disparity index is calculated & by applying the standard deviation technique the study area is divided into low, medium & high disparity regions. The disparity was 0.45 in 2001 which came down to 0.36 in 2011 (**Table-**1 & **Table-**2 and Fig 2).

Table-1: Gender Disparity Index (GDI) in Literacy Rate, 2001

Blocks	% of literacy to the total population in Lucknow 2011				
	Total Literacy	Male Literacy Rate	Female Literacy Rate	Gap in Male-Female Literacy Rate (%)	Gender Disparity Index (GDI)
Mal	47.1	60.2	32.4	27.8	0.49
Malihabad	51.3	63.7	37.0	26.7	0.47
Bakshi Ka Talab	55.5	67.7	41.3	26.4	0.47
Chinhat	55.8	67.1	42.8	24.3	0.43

District (Rural)	53.9	65.9	40.1	25.8	0.45

Source: District Census Handbook of Lucknow, 2001

Areas of Low Disparity

In 2001, low disparity range (Below 0.45) was observed in 3 blocks namely Chinhat (0.43), Kakori (0.41) & Sarojaninagar (0.43). The highest rural literacy of 58.4% with 69.5% of male literacy & 45.5% of female literacy was recorded in Sarojaninagar block. In 2011 the same blocks except Sarojaninagar (0.38) i.e. Chinhat (0.33) & Kakori (0.32) were in the low disparity range (Below 0.36). This low disparity in these blocks can be attributed to good socio-economic development, high literacy, better opportunities for women, suitable environment etc.

Areas of Medium Disparity

In 2001, the medium disparity was between (0.45-0.48) range. Under this range, there were 3 blocks namely Malihabad (0.49), Bakshi Ka Talab (0.47) & Mohanlalganj (0.45). In 2011, medium disparity range (0.36-0.38), 2 more blocks were added in the range, now there were 5 blocks in total namely, Malihabad (0.37), Bakshi Ka Talab(0.37), Sarojaninagar (0.38), Gosainganj (0.36) & Mohanlalganj (0.37) (Fig 2 and **Table**-3 and 4).

Areas of High Disparity

In 2001, high disparity range (Above 0.48) was observed in 2 blocks namely Mal (0.49) & Gosainganj (0.49). The lowest literacy rate is witnessed in Mal block

with total literacy being 47.1%, the male & female literates being 60.2% & 32.4% respectively. In 2011, there was only 1 block i.e. Mal (0.40) which showed high disparity range (Above 0.38). Though, the overall iteracy was improved in the block with 64.3% with 74.3% & 53.3% as male and female literates but, the gender gap was widest with 21%.

Policy Measures

Being the largest populous state, Uttar Pradesh requires more efficient & inclusive policies to attain high literacy levels. The government needs to address the urgent needs in the education sector. To achieve socio-economic development following measures should be initiated: Education being a state subject, it is the responsibility of each state government to ensure the proper infrastructure of schools in rural areas, increase the number of teachers, incentives like textbooks, scholarships & free uniforms. The accessibility of educational facilities should be penetrated more in rural areas. All the administrative machinery at different levels should ensure proper functioning. Committees should be formed to ensure the proper utilization of funds allotted for improving literacy levels with a dedicated monitoring mechanism. (1) Social awareness campaigns should be launched to fight against the social evils existing in society like dowry the system, preference for a male child, child marriage, female infanticide, etc. The issues with education and literacy should be addressed by society as a whole. NGOs & civil society organizations play a vital role in enhancing awareness in society & educating individuals about the consequences of illiteracy (2) Due to various socio-economic constraints, the problem of early dropouts in rural areas can be observed. The National scheme Beti Bachao, Beti Padhao (BBBP) shows great success in encouraging the education of the girl child. Schemes like- UP Free Education Scheme, Kanya Sumangala Yojana (KSY), Bhagya Laxmi yojana, and Abhyudaya yojana, are important initiatives launched by the government to improve gender inequality.

'Mid-Day Meal' scheme is a scheme launched by the central government, under which mid-day meals are provided free of cost to the students of primary & junior primary schools. This programme has been a big success, but it should also focus on providing village children with sufficient nutrition & nourishment in addition to enrolling them in school. Recently, the Tamil Nadu government has supplemented midday meals in government schools with a breakfast scheme which is changing the dynamics of primary education & gross enrollment & active participation of the children in schools. (4) Job-oriented skill training, workshops, etc at secondary & higher secondary levels for girl children should be conducted to minimize gender discrimination. Vocational courses for- farming, dairy farming, handloom & textiles, poultry farming etc should be provided to the women of rural areas.

Conclusion

The paper is an attempt to evaluate the existing patterns of literacy rate & the level of the male-female disparity in literacy in the Lucknow district. The study area witnesses an increase in literacy rate from 53.9% in 2001 to 67.8% in 2011. However, a wide gap between male & female literacy can be observed. Though great numbers of female literacy can be seen from 40.1% in 2001 to 58.3% in 2011 in the study area, female literacy still lags behind male literacy. The female literacy rate of 58.3% is lower than the literacy rate of the male 76.4% population in 2011. The lowest literacy in 2001 was recorded in Mal & Kakori block with 47.1% & 50.4% respectively & in 2011, Mal & Gosainganj block recorded the lowest literacy with 64.3%. In 2001, the largest gap in gender literacy was seen in Mal & Gosainganj block with almost the same numbers of 27.8% & 27.7% while in 2011, the maximum gender disparity in literacy was seen in the Mal block with 21%. Chinhat block recorded a higher proportion of literacy rate in the urban area. Thus, it can be concluded that there exists an inverse relation between literacy & gender disparity. The literacy gap between men and women has narrowed through time, and this pattern should be continued in the future years.

CHALLENGES FACED BY WOMEN STREET VENDORS OF VARANASI CITY

Nitish Kumar Bhardwaj and Vishal Vikram Singh

Abstract

With the increasing rate of unemployment street vending has become a source of livelihood for a larger section of population. Uttar Pradesh records highest number of vendors followed by Madhya Pradesh. Vending is a source of livelihood with low capital and a temporary structure, which fulfills the goods and services need of the public. They mostly Belongs to the lower section of the society, and don't have the opportunity, education or skill to work in formal sector. So, they operating in the informal economy with no job security and uncertainty. The aim of this paper is to study the challenges faced by women street vendors in Varanasi city. For this purpose100 women street vendors were selected through simple random sampling method. The respondents were interviewed accordingly in order to access the information. Through the survey it was found that most of the female street vendors are between age group of 30-55 years. They are mostly married and sell fruits, flowers, vegetables, food items, clothes and other groceries. These women street vendors face many problems at their home and workplace. Lack of proper sanitation, unhygienic environment, unavailability of toilets are prominent issues as well as misbehaving of police personnel and local authorities at the workplace are common. The respondents told that working late night is also not safe. As a result of the efforts made by various NGOs and organizations for years, the Government of India has focused on the plight of street vendors and has created some policy and schemes for their progress like Street Vendor Act 2014, PM SVANidhi Scheme 2020. Nevertheless, most of the street vendors are deprived of these schemes due to ignorance and accessibility.

Introduction

Despite the existence of various constitutional and legal provisions safeguarding women's employment a large number of women workers, particularly in the unorganized sector suffer from various disadvantages relating to their

working lives as well as home. In 2005 the Confederation of Indian Industries (CII) commissioned a study titled 'Understanding the Levels of Women's Empowerment in the Work Place' revealed that women constitute only 6% of total workforce in corporate houses. The percentage of women in leading managerial positions is abysmally low. Only 7% labour force is in the organized sector and 93% work in unorganized or informal sector. Most of them are in street vending and others are engaged in household activities. The reason for the employment of women in such large numbers in the informal sector is women's weaker bargaining power, low skilled labour, generally lower wages than men and lack of unionization. Street vendors are those one who buy the goods at whole sale and sell it at retail price in the streets, road side, at bus stand or at other places of decent crowd for their daily livelihood. NASVI has defined street vendors as "a person who offers goods or services for sale to the public without having a permanently build structure but with a temporary static structure or mobile stall". Street Vending is one of the most visible aspects of the informal sector and practiced globally.

The major characteristics of street vending are low level of income, ease of entry, self-employed and it involves large number of people. About 80% of the population is engaged in the street vending. It does not only provide self-employment but also a means to provide affordable and convenient service (Jaishankar and Sujata, 2016). Street vending serves as important income generating activity which gives employment to sufficient number of poor women living in urban peripheral areas or slums. Street vendors sell their goods mostly on pavement and streets. However, street vending can be considered as an integral part of rural and urban economy characteristized with specific insecurities and challenges. The contribution of street vendors in generating a considerable amount of money in to the informal sector is often a crucial factor in driving the economy. Street vendors fulfill the requirements of the society and cater to the need of a sufficient number of customers especially from middle- and lower-income class. Women can be seen doing street vending along the pavements and streets. Mostly women enter in the street vending due their poor economic conditions. Their motive is to maintain their financial condition so as to fulfill their daily needs of the family. Apart from the problem of earning money for survival, women street vendors face several issues of uncertain and insecure working conditions at the workplace. Some major issues and problems faced by street vendors are lack of support, regular threat of eviction, and harassment by local officials and authorities. According to the report of ILO, 85 % of the street vendors face several health hazards.

It includes disease like increased depression, acidity, high blood pressure and increased blood sugar and others health complications. Except this, women face problem, related to sanitation, economic pressure, social cultural challenges, adverse political conditions and operational challenges (Tambunam. 2009). During COVID- 19 period Most of the women street vendors lost the means to work and livelihood which witnessed a significant fall in their income and earnings. With the loss in employment opportunities during COVID period, many of the women street vendors were not able to shift to alternative employment opportunities and were forced to continue with the same street-vending activity.

Study Region

Varanasi lying between 82°56' E to 83°03' E and 25°14'N. (also known as kashi or Banaras) is one of the oldest living cities in the world dating back 3000 to 5000 years. Being located on the crescent shaped bank of the Ganga River it is considered as cultural and spiritual capital of India. Due to high population growth and rapid development of the city during the decades of 1991 and 2000 it became a million city. Rapid urbanization has led to many urban problems such as pollution, living space, sanitation and unemployment. The increasing population and faulty government policies has forced a large segment of people towards the informal sector. In this Street vending has become a major source of livelihood for the people living in peripheral urban spaces. These people face several issues and challenges at their workplace. The present study is an attempt to highlight those issues and provide a better understanding of the factors operating therein.

Objectives

(1) The present study seeks to provide a better understanding of the demographic characteristics of women street vendors in the study area.

(2) To know the socio-economic and political constraints of women street vendors in Varanasi city.

(3) To evaluate the relevant issues and challenges faced by women street vendors at their Workplace and to provide insights of policy implications and remedial measures to deal with the issues and challenges faced by women street vendors.

Database and Methodology

The study is entirely based on primary data which have been collected through personal level survey in the study area. A structured interview schedule

containing pertinent questions related to the issues and problems faced by women street vendors in the Varanasi city was used in order to access the required data. Some open-ended questions were also incorporated in order to know the views and opinions of the women street vendors towards government policies, officials and local authorities. For the purpose of study, the samples have been choosen from five administrative zones of the Varanasi city namely, Varuna par, Kotwali, Bhelupur, Aadampur and Dashaswamedh. On the basis of simple random sampling method 20 sample have been taken from each zone and interviewed accordingly. Total 100 respondents have been interviewed and data have been analysed in order to draw conclusions. Data have been analysed and interpreted with the help of different tools like MS Excel 2012 and SPSS-22 version. Maps, charts and diagrams are incorporated wherever necessary. Maps have been prepared with the help of ARC GIS 10.3 software.

Results and Discussion

Results have been derived from the responses collected through the interview schedule which contained questions related to the respondent's demographic characteristics and the challenges being faced by them at their work place. An attempt has been also made to suggest the remedial measures and expected solutions.

Age; During the survey it was found that majority of the women street vendors were above 41-60 age-group. In most of the cases she herself was the head of the house and therefore they had taken the responsibility of earning the bread for themselves and their families. They also take care of other amenities in the house. It was also observed that 22 percent of women street vendors were between age group of 51-60. The younger age groups witnessed comparatively low proportion of women street vendors. Feeling unsafe is major factor behind such low proportion of women street vendors in the younger age groups. Being asked, the vendors told that their husband either do farming in the village or earn in the outer region through daily wages or help them in vending along road side, streets and pavements.

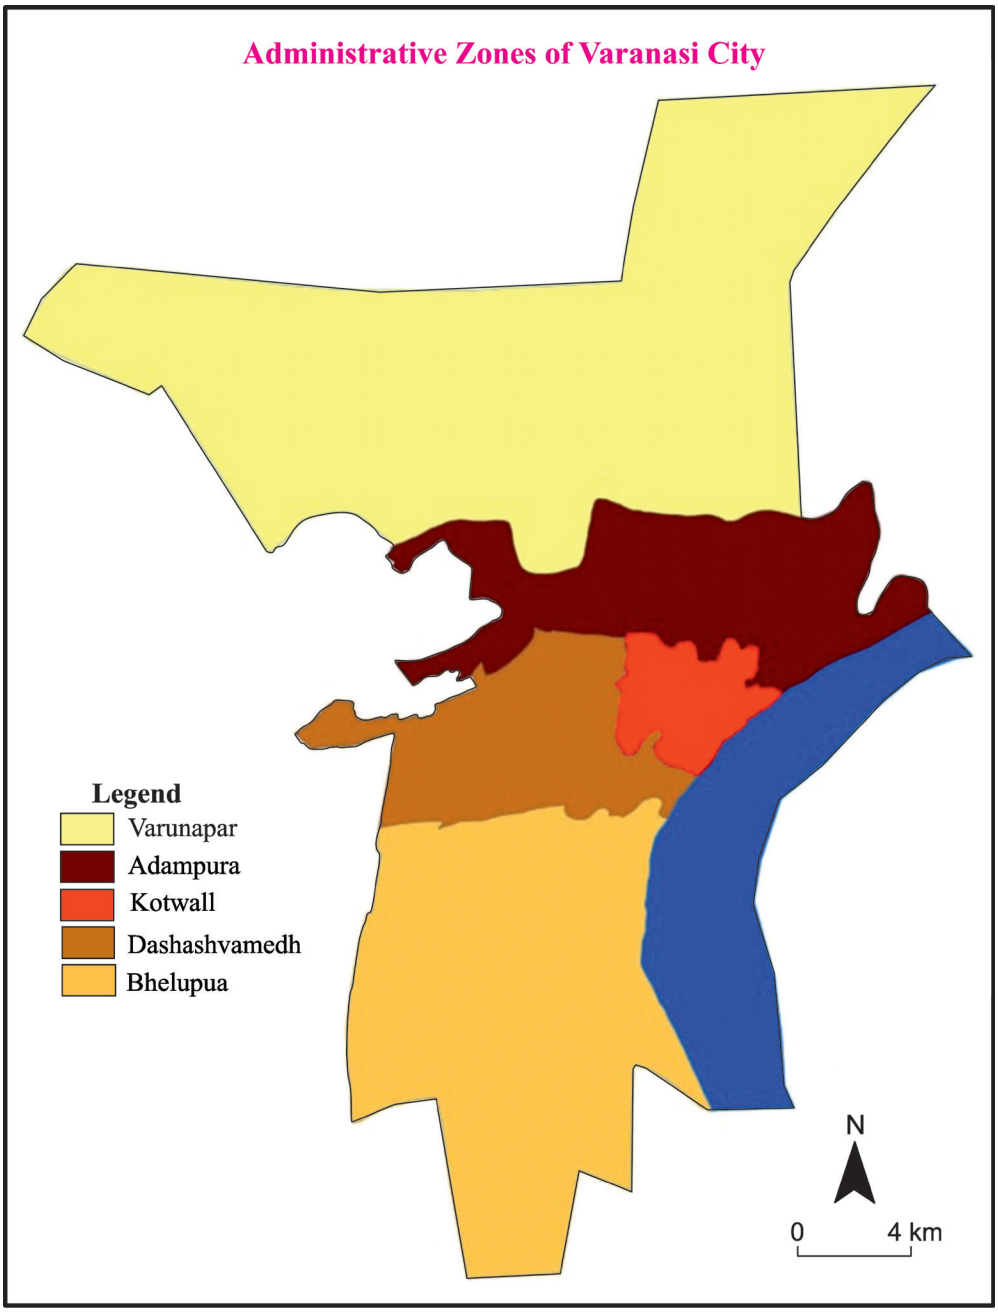
Marital Status: Marital status is another significant demographic characteristic which was considered during the survey. The data recorded reveales different nuptial categories of women street vendors in the Varanasi city. The highest percentage (78 percent) of women street vendors are married followed by 8 percent of unmarried women. This is because of the fact that married women street vendors of higher age groups feel more confident regarding feeling safe at the workplace in comparison to married and und unmarried women of the younger age groups.

Another significant demographic feature of the table is the proportion of widowed women street vendors in the city. It was recorded that 13 percent of women street vendors were widowed. This is the bitter fact of the Indian society that whenever a woman is widowed, she becomes economically vulnerable which forces her to do vending and other low level economic activities to run the livelihood of her family. Type of Street Vending: The responses during the survey portraits the proportions of women street vendors engaged in different stuffs in different zones of Varanasi city. It was observed that highest percentage (37 percent) of women street vendors were engaged in selling vegetables and fruits along the pavements and streets followed by 25 percent in tea and food stuffs while 25 percent of them were engaged in selling flowers and garlands. The highest proportion of women street vendors in selling vegetables and fruits along with other food items is due to easily availability of these items in the market. Another significant factors behind this may be the good returns and affordability of these items.

Access to Workplace Amenities

During the field survey the data was also collected regarding access to work place amenities like toilet facilities, availability of fresh drinking water, storage and alike in order to measure hygiene and sanitation at work place. The results found are quite disgusting that above 90 percent of women street vendors don't have facility of toilets, safe drinking water, storage and other amenities. Due to working in such a unhygienic environment the women street vendors are prone to several diseases like stress, hypertension and acidity (**Fig.** 1).

Awareness about Right and Interests: Responses were also recorded regarding the awareness of women street vendors towards their rights and interests. The data reveals that Majority of the respondents (88 per cent) disagree that the government protects the rights and interests of women street vendors. Another significant factor behind such situation is the ignorance and high level illiteracy among the women street vendors. Due to this most of the women street vendors are unaware of their rights and are often harassed by government officials and local authorities. Because they are illiterate or less educated and have no information about the government's plans and policies made for street vendors; local police exploit them at the workplace. These factors play crucial role behind the vulnerable conditions of women street vendors in Varanasi city. Proper measures and steps should be taken in order to safeguard the rights and interests of women street vendors in the study area. Harassed and Abused by the Authorities: In order to analyses the factors behind the vulnerable condition of women street vendors in Varanasi city



Administrative Zones of Varanasi City
Legend
Varunapar
Adampura
Kotwall
Dashashvamedh
Bhelupua
N
0
4 km

Fig. 1

the responses were also recorded know the status of being harassed, teased or abused by concerned government officials and local authorities. The study reveals that 70 per cent of the women street vendors in the city reported that they are being harassed and abused by the concerned city authorities or police at the workplace while 30 per cent of the respondents said that they are not being harassed by the city authorities or police. Being ignorant of their rights and safeguards provided by government policies these women street vendors are prone to exploitation through several means by police and local authorities. (**Fig.** 1)

Security at Work Place: Among the several significant constraints of women street vendors the prominent one is security at the workplace. There are sufficient number of studies which advocates for the safety of women street vendors while working late hours in the night. Due to several efforts government has drafted policies to safeguard the interests and rights of the women street vendors. In spite of this insecurity is the major issue for the women street vendors while working late hours in the Varanasi city. On the basis of responses recorded during the survey it was observed that 92 per cent of the women street vendors in the Varanasi city do not feel safe and secure while working late hours in the night. While only 8 per cent said that they feel secure even while working late hours in the market. As mentioned above security is the key issue among the several socio-economic barriers being faced by women street vendors in the Varanasi city.

Health Issues

Many studies reveal that street vendors work in severe unhygienic environment because of this they are prone to several diseases. In the Varanasi city an effort was made to record the responses of the women street vendors in order to know the status of hygiene and health issues. However the study conducted reveals that 41per cent of the women street vendors stated that they have health related disorders like blood pressure, Sugar, deafness, low vision while 59 per cent of the respondents said that they don't have any kind of health issues. As the study found that women street vendors don't have proper sanitation measures like toilets, fresh drinking water and air they are prone to several diseases.

Remedies

Some responses were also recorded in order to know the status of remedial measures. The data reveals quite disgusting factor that the women street vendors in Varanasi city don't believe that their status can be improved through policies and safeguards provided by government or some NGO organization. Most of the

women street vendors are of the view that their status can be improved only by themselves. According to the responses recorded 12 percent of the women street vendors said that their condition can be improved with the help of government initiatives, 15 percent said, it can be improved with the help of NGOs & their association and lastly, 73 percent said that it can be improved only through him/her self. The recorded responses show that there are many drawbacks and Loopholes which need to be taken care of while drafting and implementing the policies for women street vendors. It is also a bitter fact that association and NGO organization are not working well.

Conclusion

As mentioned, total 100 women street vendors were interviewed and their responses were recorded. 1. One significant demographic feature is that majority of women street vendors are between age group of 41-60. It may be because of the fact that women in comparatively older age groups feel more confident and safer at the workplace than those who are unmarried or in younger age groups. 2. Because of easy availability of in the local market majority of the women street vendors in Varanasi City were engaged in selling vegetables and fruits. Very few Of them are engaged in other economic activities. 3. Major socio-economic and administrative constraints being faced by the women street vendors are those of their basic necessities and amenities at the workplace like lack of hygienic space, toilets, feeling unsafe at the workplace during late hours and continuous harassment by local authorities, government officials and police. 4. The responses recorded during the survey reveals the fact that the policies and safeguards provided by government have some loopholes and drawbacks due to this most of the women street vendors are unaware of these policies. Other factors behind this may be the ignorance and illiteracy among the women street vendors or lame efforts of government officials in implementation and execution of these policies. However, it has been also reported that few of the women street vendors are receiving some kind of benefits from the government and they are keenly looking forward for their support and guidance. 5. There is a urgent need to take care of the issues and challenges being faced by the women street vendors in Varanasi city. The policies and safeguards should be implemented in a very effective manner so that it can cover most of the women street vendors. Other remedial measure which is to be taken is the proper education of the women street vendors so that it can enable them towards their rights and interests. Other amenities which are necessary at the workplace should also be taken care of like permanent place for vending, proper sanitation and hygiene etc.

BALANCING AGRICULTURAL DEMAND AND WATER RESOURCES: A STUDY OF IRRIGATION INTENSITY TRENDS IN MANDYA DISTRICT, KARNATAKA

Dr. Vishwanath, B.C. and Harish, H.S.

Abstract

Irrigation intensity in agricultural regions is influenced by various factors, including water source, quantity and quality, and channel network density. This study explores irrigation intensity variations in Mandya District, Karnataka, over the period 1991-2017, considering factors like cropping patterns, land-use efficiency, and adoption of cultivation methods. Mandya District, located in South India, is dissected into seven taluks. The study examines changes in irrigation intensity across these taluks, highlighting the district's geographical and agricultural diversity. The primary objective is to assess irrigation intensity changes in Mandya District from 1991 to 2017. Using historical documents and government reports, the study traces the evolution of water management in Mandya. Statistical analyses of net irrigated areas for 1991, 2001, and 2017 reveal shifts in irrigation methods. The intensity of irrigation is calculated using the ratio of net irrigated area to net sown area. Taluk-wise analyses and categorizations are conducted to understand spatial patterns. The findings indicate a significant increase in irrigation intensity from 41.4% in 1991 to 75.7% in 2017. Taluk-wise analyses reveal dynamic changes, with Mandya taluk consistently showing high intensity. Positive changes are attributed to canal construction, increased cultivable areas, well irrigation, and advancements in agriculture. Despite advancements, certain areas in Mandya remain rainfall-dependent, impacting crop productivity and income inequality. The study suggests utilizing rainwater through farm ponds and watershed structures. Emphasizing efficient canal water usage, including lining distributaries and field channels, is recommended. The district irrigation plan aims to mitigate drought, expand irrigated areas, and optimize water usage through innovative cropping patterns. This research provides valuable insights into the evolving landscape of irrigation intensity in Mandya District, offering a foundation for sustainable water resource management strategies.

Introduction

The term "irrigation intensity" usually refers to the amount of water used to irrigate a specific area of land. It measures how effectively water is used during the irrigation process. Irrigation intensity is commonly expressed in millimeters or inches and is calculated by dividing the total volume of water applied by the irrigated area. Irrigation intensity varies across agricultural regions due to a variety of factors such as irrigation source, water supply quantity and quality, and water channel network density. Cropping seasons, crop types, and other factors all have an impact on it. Cropping patterns, land-use efficiency, area yield efficiency, and the adoption of improved cultivation methods all benefit from increased irrigation intensity. The intensity of irrigation has a significant impact on agricultural productivity, water conservation, and environmental sustainability. Water stress and reduced crop yields can result if the amount of water applied is insufficient for the needs of the crops. Inadequate irrigation can also cause soil degradation and harm the agricultural ecosystem's overall health. Excessive irrigation, on the other hand, can result in waterlogging, soil salinity, and water resource waste. High irrigation intensity can also contribute to environmental issues like runoff, fertilizer and pesticide leaching, and negative impacts on local water bodies. Irrigation intensity is typically low in areas with limited infrastructure for expanding irrigation or where irrigation is used as a precautionary measure to address moisture scarcity in areas prone to heavy rainfall. All else being equal, irrigation intensity increases with decreasing rainfall and decreases with increasing rainfall in agricultural contexts. Irrigation intensity is typically low and negligible in rain-fed areas with constrained surface water, saline subsoil, and hilly or undulating topography. Typically, irrigation intensity is expressed in two ways, namely, the ratio of gross irrigated land to net irrigated land. The proportion of net irrigated land to net sown land.

Study Region

Mandya District is located in the South Indian Peninsula on the Mysore plateau, between 76° 19' and 77° 20' East Longitude and 12° 13' and 13° 04' North Latitude. It is bounded to the north by Hassan and Tumkur districts, to the east by Tumkur and Bangalore districts, to the south by Mysore district, and to the west by Hassan and Mysore districts. Mandya is the 19th largest district in Karnataka, covering a total area of 191,976 square kilometres (**Table-**1). Nagamangala, K.R. Pet, Mandya, Malavalli, Maddur, Pandavapura, and Srirangapatanna are the district's seven taluks. Notably, Nagamangala has the largest geographical area at 1,044.7 square kilometres, accounting for approximately 21% of Mandya's total area.

Table-1: Talukwise Irrigation Intensity in Mandya District 1991-2017

Sl No	Taluk	1991			2001			2017			Irrigation intensity change in 1991-2017
		Net Irrigated area	Net Sown area	Intensity of Irrigation in %	Net Irrigated area	Net Sown area	Intensity of Irrigation in %	Net Irrigated area	Net Sown area	Intensity of Irrigation in %	
1	K.R. Pet	16865	38890	43.4	20263	48646	41.6	25016	40407	61.9	+ 18.5

	Total	99563	240779	41.4	106952	247388	43.2	127188	168110	75.7	+ 34.3

Source: Data compiled from Directorate of Economics and Statistics, Government of Karnataka, Bangalore.

Despite having a higher population density, Mandya taluk ranks fourth in terms of area, covering 699.06 square kilometres. Srirangapatna, on the other hand, has the smallest area, accounting for only 6.9% of the district's total area.

Objective

The present paper attempted to study the irritation intensity in Mandya district, Karnataka.

Methodology

In order to conduct a thorough investigation, I reviewed a large body of existing literature on water resource utilization, irrigation methods, and disparities within comparable geographic regions. My focus was on the Mandya District in South India, a region chosen for its importance in terms of water resource imbalances and diverse irrigation practices. I traced the evolution of water management in Mandya District using historical documents, research papers, and governmental reports. Supplementary data was obtained from the Government of Karnataka's Directorate of Economics and Statistics, which provided critical historical records of irrigation sources and trends. I assessed changes in net irrigated area using statistical analyses for the years 1991, 2001, and 2017, using percentages to identify shifts in the dominance of specific irrigation methods. I investigated specific instances of water resource utilisation within Mandya District using a case study approach, delving into local contexts, socioeconomic factors, and infrastructure development nuances. The findings were systematically compared to historical data, revealing insights into changes in irrigation methods, areas covered, and the overall landscape of water resource utilisation in the Mandya District. In the present study researcher has used the second method to express the intensity of irrigation in the region. Here the intensity has been calculated with the help of following formula.

$$\text{Intensity of irrigation} = \frac{\text{Net irrigated area}}{\text{Net sown area}} \times 100$$

Result and Discussion

The present study reveals that the variation in the intensity of irrigation. **Table-**1 and 2 explain that the Mandya district has about 41.4% of irrigation intensity in the year 1991 and it has been increased to 43.2% in the year 2001, further it has increased to 75.7% in 2017 (**Fig.** 1 and **Table-**2). The analyzing of spatial pattern of intensity of irrigation in Mandya district shown in **Table-**2 there is a significant change has been observed in the intensity of irrigation in the region from 1991-2017,

Source: Computed by Authors

the taluk wise analysis reveals that in 1991 Srirangapattana (63.8%) taluk have recorded high (More than 60%) intensity of irrigation. The medium irrigation intensity (30%-60%) is noticed Mandya (55.9%), Maddur (50.6%), Malavalli (43.7%), K.R. Pet (43.3%) taluks of the region. The taluks like Nagamangala (7.3%) and Pandavapura (29.1%) fall in low intensity of irrigation (less than 30%). The taluk wise analysis reveals that in 2001 Mandya (68.6%) taluk have recorded high (More than 60%) intensity of irrigation. The medium irrigation intensity (30%-60%) is noticed Srirangapattana (59.8%), Maddur (56.7%), Malavalli (42.4%), K.R. Pet (41.6%) and Pandavapura (39.6%) taluks of the region. The Nagamangala taluk (10.2%) fall in low intensity of irrigation (less than 30%) (**Fig.** 1). The taluk wise analysis reveals that in 2017 Mandya (84.6%), Malavalli (70.3%), Srirangapattana (69.4%), Maddur (69.3%), Pandavapura (66.7%), K.R. Pet (61.9%) taluks have recorded high (More than 60%) intensity of irrigation and Nagamangala taluk (21.3%) fall in low intensity of irrigation (less than 30%). In the study period there is positive change in irrigation intensity. It is because of the progress in the construction of new canals to provide water for tank irrigation and every year more and more cultivable areas are brought under cultivation and also increased number of well irrigation and advanced agriculture due to development

of transportation facility. During the study period (1991-2017) the district as whole has shown a significant change in the intensity of irrigation. These taluks have shown a positive change in the intensity of irrigation. It is clear that during the year 1991 the irrigation intensity was about 41.4% and it increased to 75.7% in 2017. The net increase in the volume of intensity of irrigation was about 34.3%. The taluk wise changes in the intensity of irrigation during the study period depicts that only Pandavapura taluk have shown high percentage of change i.e., 37.6%, Srirangapattana taluk have shown less change in intensity of irrigation i.e., 5.6%.

Taluka wise Analysis

The intensity of irrigation in Mandya district increased from 41.4% in 1991 to 43.2% in 2001 and further to 75.7% in 2017. The spatial pattern analysis indicates a significant change in irrigation intensity from 1991 to 2017. In 1991, Srirangapattana taluk had the highest intensity of irrigation (63.8%), classified as high. Mandya, Maddur, Malavalli, and K.R. Pet taluks had medium intensity (30%-60%). Nagamangala and Pandavapura taluks had low intensity (less than 30%). In 2001, Mandya taluk now has the highest intensity (68.6%). Srirangapattana, Maddur, Malavalli, K.R. Pet, and Pandavapura taluks had medium intensity. Nagamangala taluk remained in low intensity. In 2017, Mandya, Malavalli, Srirangapattana, Maddur, Pandavapura, and K.R. Pet taluks recorded high intensity. Nagamangala taluk remained in low intensity. Positive changes in irrigation intensity are attributed to the construction of new canals, increased cultivable areas, well irrigation, and advanced agriculture facilitated by improved transportation. (**Fig.** 1) The overall district experienced a significant increase in irrigation intensity from 41.4% to 75.7% during 1991-2017, representing a net increase of 34.3%. Pandavapura taluk showed the highest percentage change (37.6%). Srirangapattana taluk showed the least change in irrigation intensity (5.6%).

Conclusion

Despite being irrigated by two commands, Mandya district has 1.46 lakh ha fully dependent on rainfall. The crop productivity in such areas is limited to dry crops like ragi, horsegram, avare, maize, groundnut etc. Irrigated area predominantly grows paddy and sugarcane. Irrigated farmers invariably record higher incomes, while farmers from dry areas continue to reel under poverty. The inequality of growth rate in income of these two distinctly different areas has not been able to be neutralised by any other sources of irrigation, including well irrigation. Mandya district has only 5000 ha under bore well irrigation, while open wells irrigate around 6800 ha.

However, there is excellent scope to harvest rain water in smaller structures like farm ponds, check dams, nala bunds and other water shed structures in un-irrigated areas. The present district irrigation plan focuses on use of rain water more efficiently by various water shed structures for protective irrigation as a measure of drought mitigation. Further, nearly 630 tanks are available in Mandya district. They have created irrigation potentiality of around 16000 ha. But, there is need to utilise this tank irrigated area, by effective measures like tank desilting, renovation or filling tanks with canal/ lift irrigation schemes. There is general lacuna in utilizing the canal water, in terms of efficiency. Most distributaries/ field channels unlined and there is vast scope to improve the irrigation efficiency by proper lining to these structures, and attending to other canal maintenance works timely. This way, the created potential can be utilized fully. All these aspects are considered, while Mandya district Irrigation Plan is developed- with the ultimate objective of utilizing the created potential with expansion, wherever possible irrigated area and drought mitigation in non- command areas. A new cropping pattern involving regulated sugarcane cultivation and reducing other water intensive crops can save large quantity of water and this can ensure water availability to tail end areas.

WORKFORCE ASSESSMENT OF PRINCIPAL EMPLOYEES AND AGRICULTURAL WORKERS IN KANNAUJ DISTRICT, UTTAR PRADESH

Kalpana Devi and Dr. Shashi Bala Singh

Abstract

The research focuses on assessing the workforce dynamics within Kannauj district for the year 2021-22, emphasizing the distribution and prevalence of principal employees and agricultural workers across its development blocks. The study examines the proportions of principal employees in comparison to the total population in various blocks. Umaruda and Gugarapur exhibit notably high percentages, signifying substantial principal employment, followed by Talgram with a significant figure. Haseran and Jalalabad portray a slightly lower ratio, while Kannauj, Saurikh, and Chhibramau demonstrate relatively comparable patterns. These percentages elucidate the distribution and concentration of principal employees, showcasing varying proportional representations among the development blocks. Moreover, the study investigates the proportions of agricultural workers within the total principal employee workforce across the district. Areas like Saurikh, Haseran, and Chhibramau showcase high percentages of agricultural workers among the principal employees, indicating significant agricultural employment. Umaruda and Kannauj also demonstrate substantial agricultural labour presence, while Gugarapur shows a slightly lower ratio. Talgram and Jalalabad exhibit relatively fewer agricultural workers compared to the total principal employees in those specific blocks. These percentages offer insights into the distribution and concentration of agricultural workers concerning the total principal workforce across different development blocks in the Kannauj district, reflecting distinct levels of agricultural employment across these regions during the specified period. The study utilized data sourced from official government records, statistical reports, and surveys conducted by relevant authorities, encompassing population figures, principal employee counts, and specific employment statistics for agricultural workers. The research aims to depict variations in employment patterns and workforce concentrations, focusing on the proportional representations of principal employees and agricultural workers across the district's diverse blocks during the specified period.

Introduction

Kannauj district in the year 2021-22 witnessed varied proportions of principal employees and agricultural workers dispersed across its distinctive development blocks, portraying notable employment diversities. This study scrutinizes the intricate dynamics of workforce distribution within the district, focusing on the prevalence of principal employees and agricultural workers across different regions. The analysis reveals significant disparities in the proportion of principal employees concerning the entire population across various development blocks. Umaruda emerges as a frontrunner, boasting the highest percentage of principal employees at 27.44%, closely shadowed by Gugarapur at 27.07% and Talgram at 26.59%. Contrastingly, Haseran, Jalalabad, Kannauj, Saurikh, and Chhibramau exhibit relatively lower percentages, portraying a discernibly varied distribution of principal workers within these areas. Moreover, the study unveils an intriguing variation in the proportion of agricultural workers relative to the total principal employee workforce across the district's development blocks. Saurikh, Haseran, and Chhibramau stand out with notably high percentages of agricultural workers among the principal employees, ranging from 84.74% to 84.13%. Umaruda and Kannauj display substantial agricultural labour presence, whereas Gugarapur, Talgram, and Jalalabad depict relatively lower ratios of agricultural workers compared to the total principal employees in their respective blocks. This research draws upon comprehensive data sourced from official government records, statistical reports, and surveys conducted by relevant authorities. Employing a meticulous methodology involving precise demographic data collection, and cross-referencing of population figures with employment records identified principal employees across development blocks. Additionally, statistical calculations discerned the distribution and concentration of agricultural labour within the principal employee workforce across diverse areas within the Kannauj district.

Objectives

(1) The primary objective is to analyze the distribution of principal employees across different development blocks within Kannauj district during 2021-22.

(2) To examine the variation in the proportion of agricultural workers relative to the total principal workforce across different development blocks.

Database and Methodology

The data used for analyzing the distribution of principal employees and agricultural workers in the Kannauj district for the year 2021-22 was sourced from

official government records, statistical reports, and surveys conducted by relevant authorities. This data includes information on the total population figures, the count of principal employees in various development blocks, and the corresponding employment statistics specific to agricultural workers. The methodology involved collecting accurate demographic data from the census and employment records for the Kannauj district. The total population figures were cross- referenced with employment records to identify principal employees in different development blocks. The percentage of principal employees relative to the entire population was calculated for each block to ascertain their proportional representation. Analyze agricultural employment, the total count of agricultural workers within the principal employee category was identified based on official records. The percentage of agricultural workers concerning the total principal employees in each development block was computed to discern the distribution and concentration of agricultural labor across various areas within the district. This analysis involved statistical calculations, ratios, and percentage computations to understand the representation of principal employees and agricultural workers concerning the total population and the total principal employee workforce, respectively. The study aimed to depict variations in employment patterns and workforce concentration across the diverse development blocks within the Kannauj district for the specified period.

Results and Discussions

Principal Employees

In the Kannauj district for the year 2021-22, the percentage of total principal employees about the entire population varies across its development blocks. Among these blocks, Umaruda stands out with the highest percentage, comprising 27.44% of principal employees. Compared to the overall populace. Gugarapur closely follows with 27.07%, demonstrating a significant presence of principal workers within its boundaries (**Table-**1 and **Fig. 1**). Talgram maintains a substantial figure at 26.59%, indicating a considerable proportion of principal employees relative to the population. As we move further, Haseran and Jalalabad exhibit 24.5% and 24.32% percentages, signifying a noticeable but slightly lower ratio of principal workers compared to the total population. The district's administrative centre, Kannauj, registers a percentage of 23.87%, suggesting a slightly lower presence of principal employees concerning the overall populace (**Fig. 1** and 2). Overall, these percentages delineate the distribution and concentration of principal workers across the development blocks within the Kannauj district, portraying variations in their proportional representation concerning the total population for the specified period.

Agricultural Workers

In the Kannauj district for the year 2021-22, the percentage of total agricultural workers in comparison to the total principal employees varies across its development blocks. The blocks of Saurikh, Haseran, and Chhibramau exhibit the highest percentages, with 84.74%, 84.55%, and 84.13% respectively. This indicates a significant portion of agricultural workers about the total principal workforce within these areas. Umaruda and Kannauj showcase percentages of 83.71% and 83.69% respectively, signifying a substantial presence of agricultural workers among the principal employees within these blocks. Gugarapur, with a percentage of 79.96%, with the highest percentage of principal employees at 27.44%, indicating a significant presence of this workforce category in comparison to the total population. Gugarapur and Talgram followed closely, showcasing noteworthy figures of 27.07% and 26.59% respectively, underlining substantial concentrations of principal employees in these regions. Haseran, Jalalabad, Kannauj, Saurikh, and Chhibramau exhibited percentages ranging from 23.62% to 24.5%, depicting a lower but noticeable representation of principal employees relative to the overall populace. The findings demonstrate varying degrees of proportional representation of principal workers across the development blocks, signifying localized employment patterns within the district. Saurikh, Haseran, and Chhibramau emerged as areas with the highest percentages of agricultural workers among the total principal employees, ranging from 84.13% to 84.74%. This signifies a predominant agricultural workforce in these regions. Umaruda and Kannauj exhibited substantial proportions of agricultural workers at 83.71% and 83.69% respectively indicating a significant presence of agricultural labour within the principal employee category. Gugarapur displayed a considerable but slightly lower ratio of agricultural workers at 79.96% compared to the total principal employees,

showcasing a moderate agricultural employment level. Talgram and Jalalabad depicted relatively lower proportions of agricultural workers at 77.62% and 75.86%. Overall, these findings provide valuable insights into the employment patterns and the prominence of principal employees and agricultural workers across diverse development blocks within the Kannauj district, shedding light on the multifaceted nature of employment dynamics within the region.

Conclusion

In conclusion, the analysis of principal employees and agricultural workers across the development blocks within the Kannauj district for the year 2021-22 offers valuable insights into the employment landscape of the region. The findings highlight distinctive patterns in the distribution and concentration of principal employees and agricultural workers, underscoring the variations in their proportional representation concerning the total population and the total principal employee workforce. The examination of principal employees revealed significant disparities across development blocks, with Umaruda, Gugarapur, and Talgram recording notably higher percentages compared to other areas. These figures depict areas with substantial employment in non-agricultural sectors, suggesting a potentially diverse employment landscape with varying opportunities in industries beyond agriculture. Understanding the dynamics of principal employees and agricultural workers across different blocks is crucial for informed policy formulation and resource allocation, aiming to address regional disparities, promote inclusive growth, and enhance overall socio-economic development within the Kannauj district. Further research and ongoing monitoring of employment patterns will be vital to track changes, identify emerging trends, and implement strategies that foster balanced and inclusive development across the region's diverse socio- economic landscape.

DYNAMICS OF ELECTORAL BEHAVIOR OF PANCHAYAT ELECTION IN NADIA DISTRICT, WEST BENGAL

Dr. Nizamuddian Khan, Dr. Firoj Biswas and Dr. Mostafijur Rahaman

Abstract

The present study investigates the events and circumstances that shape the voter's decisions and their involvement in the electoral process. It also aims to analyze factors that have affected electoral politics and voting behavior in the Nadia District Panchayat election. India's geo-political, socio-economic, cultural, and religious conditions played an important role in the formation, identity, and growth of the political parties in West Bengal. The present study deals with the comparative analysis of the major political organizations and their role in future political developments in the province. This research article also provides a deep political insight into the nature and quality invested in the leadership of the West Bengal political parties. The paper analyzes the analytical overview of Nadia's electoral politics from the 2008 to 2018 Panchayat elections. The study examines the causes of the Trinamool Congress's landslide victory in the Nadia district elections and why residents overwhelmingly voted for the Maa Mati Manus model of development promised by the party in the state's Panchayat election. The present study is based on both Primary and secondary data sources and adapted the qualitative and quantitative methods. The fundamental approaches include participatory research methods, narratives, discourses, and grounded theory. The data has been analyzed and interpreted with the help of various statistical methods like Factor Analysis, Correlation, and cartographic techniques for analyzing data like percentages, choropleth, line Graphs, and Arc GIS 10.2. It is being observed that political party-based association, local groupings, language, class, factors of caste, social welfare policy, ideology, and religious identities are the main contributing factors in defining the trend of voting behavior in Nadia District, West Bengal.

Introduction

Democracy embodies public participation and people empowerment necessary to address the power inequities in social, economic, and political spheres

(Bandyopadhyay, 2012). It affects real change in society. Democratic participation of the grassroots in policy formulation and execution is necessary to bridge the gap between the people and the policy-makers at the highest levels (Dasgupta 2020). The decentralization of state power is essential to ensure developing societies' democratization (Biswas & Mondal 2019). Therefore, the Panchayat election is an integral part of the decentralization and democratization process in the rural areas of India. The village Panchayat existed even before independence, but they were unofficial, informal bodies without significant power. After independence, reference to the village Panchayat in the Directive Principles of State Policy of the Indian Constitution did not give much leeway to Panchayat formation in the country. "The states shall take steps to create village Panchayat and invest them with such rights and authority as necessary to allow them to function as self-government units," the Indian Constitution's Article 40 declared. Long after the adoption of the Indian Constitution, the Panchayats were recognized as an important political tool for involving the vast majority of the rural population in public policy-making at the grassroots level. The idea of the Panchayati Raj system has been prescribed in the preamble of our constitution, which speaks about the right of liberty of thought, expression, belief, faith and worship, equality of status and opportunity, fraternity, as well as to participate in all types of functions and to have faith in any religion (Banerjee, 2012).

Local government strengthens the foundation of democracy. It links people at the grass-root level and the central or state level. The basic idea behind the formation of Local Government is people's participation in their day-to-day developmental activities. But elections are examined from various angles, including political, social, cultural, and geographic ones. A politically organized community's socio-cultural aspiration is reflected in its elections. Caste and religion are the main variables affecting voters' political participation and casting their ballots. Caste issues, however, have largely taken control of political participation in Indian states after the Mandal Commission Report's 1991 recommendations (Jeffrey & Young, 2012), most notably in northern states. Though linked with the electoral politics in the West Bengal political space, it can be claimed that as a social space, Bengal has a very different political and cultural ethos rooted in the identity of place. From the very perspective of humanistic geography through phenomenological inquiries, the place and lived experiences of "beings" largely control the "subjectivity" of electoral responses. Bengal can be adjusted to this theoretical frame of place connections because of its specific genre. However, political movements like the Renaissance,

social reform, and the communist-peasant movement further enhanced the state's political value on the phenomenological–existential ground—the persistence of social movements caused normative standardization and politicized this particular place (Biswas et al 2018). The Left Front government has fostered an environment where caste and religious politics are no longer valid, in line with the Marxist theoretical framework that only applies to superstructure (Bandyopadhyay, 2012). When the Left Front lost its majority in the Panchayat election for the first time since 1975, West Bengal politics underwent a significant upheaval. The primary supporters of the left, such as landless and marginal landowners, Scheduled Castes (SC), and Scheduled Tribes, are becoming more anti-incumbent due to increased accountability constraints brought on by changes in voter characteristics and more substantial governance failures. New youthful voters, aggressive anti-incumbency, and the Nandigram and Singur issue significantly altered West Bengal's political scene (Chatterjee, 2018), and the Nadia district was no exception. Hence, the long-term regime of the left front subsided the caste issue in electoral politics in Bengal. However, "class" was a key component of social stratification during the communist regime. Class constitutes the central focal theme in political discourse. The concept of "class" offers a contemporary foundation for political parties founded on Marxism.

However, it is believed that the left's demise has allowed identity politics; significantly, caste and religious identities are centrally involved in post-communist West Bengal electoral politics. Combined efforts of Abdur Razzak Mollah, a former member of the Communist Party of India (Marxist) CPI (M) and current minister of the AITMC and Matua Mahasangha helped Mamata Banerjee win the 2013 and 2018 Panchayat elections (Biswas et al 2022). In 2018, the Bhartiya Janata Party (BJP) structured planned electoral mobilization techniques to mobilize the Hindu voters in West Bengal (Palshikar, 2015). Additionally, the BJP, led by Narendra Modi, made a conscious effort to intermix pan-national identity, nationalism, and economic developmental issues (Shastri, 2019). He nurtured the idea that nationalism is correlated to Hindutva's national frame. Developmental issues were a fundamental drive within the electoral principles. The BJP's success in the 2018 Panchayat elections is notable for the geographic scope of its triumph, the increase in vote share, its capacity to convert votes into seats, and the broad socio-economic coalition that made this victory possible. However, recent observations of the Nadia district's political culture have revealed several traits. The communal versus non-communal fault line is one of the most important political fault lines in West Bengal.

The "communal" viewpoint frequently asserts that India's nationhood is founded on the Hindu community's cultural, religious, and ethical practices. The non-communal perspective, in contrast, holds that India's nationalism is not based on any particular community or culture. The socio-cultural existence of India is increasingly complicated and pluralistic as a result. The dominance of regional parties and the continued rise of national parties are reflected in how Nadia politics have changed over the past ten years. However, in recent years, caste and religious affiliation have been important factors in the Nadia election. Power-driven identity politics damage the ideal of democracy and draw attention away from other socio-economic problems, including unemployment, poverty, crime, corruption, the safety of women, and farmer suffering. Caste, class, and community divisions sometimes result in political violence, conflict, and tensions.

Objective

The main objective is to examine the factors that influence the voting behavior of the people in the Nadia District of West Bengal.

Database and Methodology

The present study based on both the arm of research primary and secondary source of data. The primary data constituted the significant input for the study. Primary data was collected from voters through a field survey. For that, a total of 500 voters have been selected from twenty Panchayat segments of Nadia district. In addition, direct field observations and a focus group discussion (FGD) have also been carried out to supplement the survey data. Qualitative methods and approaches are this research work's dominating tools and techniques. Participatory research methods, narratives, discourses, and grounded theory are the fundamental approaches for this study. It analyses the grounded theory of cultural space and place's identity influencing electoral behavior and its variations across the state. The study is also based on historical and analytical methods. The historical method helps understand the past experiences of electoral behavior of certain issues and challenges pertaining to voting behavior and party performances in Nadia District, West Bengal. This study is based upon secondary data sources collected from the Election Commission of India, New Delhi. The data has been analyzed and interpreted with the help of various statistical and cartographic tools and techniques like percentage. The Newspaper report, election documents, and manifesto are the archival sources consulted to explain political parties' role in the electoral campaigns and mobilization.

Results and Discussions

Electoral Politics in West Bengal with Special Reference to Nadia District

As a social space, Nadia District has produced a distinct political culture since the historical memoir. The meaning of place intrinsically nurtured its cultural evolution. Monarchical and feudal regimes have significantly influenced the political history of Nadia District in addition to democratic civic administration (Sinharay, 2012). However, the extreme political socialization of the residents of Nadia District, who predominantly reside in rural areas, largely governs the district's electoral dynamics. The people are controlled by the levels of social stratification based on caste and class identities. People will not be free but respond as members of a particular social group (McMillan 2012). Political parties use voters' cognitive frames for their electoral mobilization in this social context. However, the recent elections in West Bengal, where populist inclinations attempted to supplant the pre-existing political environment, were influenced by general influences of "waive elections" and their characteristics. Media, propaganda, and other outside entities work to instill their justification in voters' minds as "bio colonization" tools. A few political parties are trying to erode caste distinctions and make them more fluid to influence voters more broadly. Political parties make an effort to participate in accommodation politics.

They form alliances and use their identities to mobilize voters and win elections (Nath & Ray, 2022). However, religion has become a significant factor in controlling voters' imaginations and voting behavior in Bengal. Religion is one of the most important factors that can quickly mobilize a wider range of demographic compositions (Hasan 2010). Religion and caste are important tools to mobilize voters and win elections in the Nadia District. This particular emotion develops the environment of "self and other selves," "binary structuralism," and "bipolar religious order of society." Social feelings and already-existing social order serve as a ready-made canvas for political parties' electoral campaigns (Jungherr 2016). The Nadia District elections served as an important case study for empirical research on the effects of various socio-economic instruments on electoral politics. In this context, it is viable to feature these elements and their consistent impact on elections. Therefore, this study investigates the role of caste, class, religion, historical memories, iconization, and populism in the Panchayat election of the Nadia district. The political culture of the Nadia district is significantly different from that of the rest of the state. Caste and religion were declared invalid by the left-front government. Marxists are the proper form of social organization since it

offers a current framework for categorizing, organizing, and mobilizing individuals (Chakrabarty 2017). In the decline of the left as a significant force in the district, caste played an important role. In the politics of postcolonial West Bengal, no doubt left culture has produced the sense of ideological essence of electoral politics. However, caste-based identity politics has transformed the values of left politics in the state. It is a fact that caste played a significant role in Nadia district's Panchayat elections. The Matua Mahasangha's growing affiliation and support with BJP, a mainstream political party. Abdur Razzak Mollah's recent efforts to forge a united political front of Dalits and Muslims (Sinharay 2019). Although most of the left-front leadership in Bengal comes from the upper castes, the communists have always enjoyed unwavering support from the Dalits. The Dalits have never felt the need for their independent political platform. The left front's apparent awareness of his demise creates a favorable environment for identity politics. In such circumstances, West Bengal will unquestionably see a rise in identity-based political mobilization. The past election witnessed a bipolar contest between the CPIM and the AITMC.

However, the last two elections have seen the emergence of the BJP as a significant political force in Nadia district politics. The BJP performed very well in the 2013 and 2018 Panchayat elections. The inherent values of imagined identities nurtured the cognitive environment of individual voters. However, identity associations on the emotional line are short-lived and challenged by the existential reality and rooted intentionality of "self" performing in individuals as electorates (Bondi 2004, Fukuyama 2018). Caste, community, clan, and kinship are the identities drastically involved in elections for large-scale political mobilization. These variants undermine the ideal democratic spirit and divert focus from other "realistic" socio-economic issues like poverty, unemployment, crime, corruption, women's security, and farmer unhappiness. The politics of daily life geography raises political questions as emerging disparities based on caste, class, and community. It may occasionally lead to hate, conflict, and even violence. Instead, regionalism and the multi-party system have created a new political environment where voter expectations are evaluated following variances in voter consciousness and information flows (Biswas, 2022). The decline of Congress and CPIM created an atmosphere for the Bhartiya Janata Party (BJP) in the Nadia district of Bengal politics.

Electoral Trends and Performance of Political Parties in Nadia District Panchayat Election from (2008- 2018)

Our study deals with the spatial and temporal variations of electoral behavior in the three Panchayat elections in the political space of Nadia district, West Bengal.

It covers the elections of 2008, 2013, and 2018. The primary focus of the study is to identify, describe, and analyze the participation patterns and associated parameters with the help of electoral data, maps, and empirical observations. The electoral seat of a political party in the legislature reflects its relative strength and determines which party will form the government. The percentage of seats won and overall seats contested is used to measure a political party's level of success. In comparison to other political parties, Trinamool Congress had the highest success rate in the Panchayat election of 2018, with a score of 67.7 percent. It shows that, under Mamata Banerjee's leadership, Trinamool Congress enhances its electoral value by capturing voters' imaginations at a larger scale, covering a larger segment of social groups. In the 2008 Panchayet election, the Communist Party of India (CPIM) was the leading political party, winning more than 30% of the vote. However, in the 2013 panchayet election, its performance slipped. From the 2008 Panchayat elections to the 2018 Panchayat elections, the Indian National Congress's performance has declined on trends. Voter behavior in the Nadia District observed a paradigm shift from 2008 to the 2018 Panchayat elections. **Table-**1 displays the performances of political parties based on the percentage of seats and votes they got in the 2008, 2013, and 2018 Panchayat elections (**Table-**1).

Table-1: Patterns of Party Performances

Political Party	Patterns of Party Performances					
	2008		2013		2018	
	No of Seats	% of Votes	No of Seats	% of Votes	No of Seats	% of Votes
CPIM	891	28.22	547	22.16	340	16.2
AITMC	809	30.22	1384	39.3	1595	44.79
INC	650	14.3	515	13.12	379	3.61

SUCI	26	4.7	20	1.8	11	0.8
CPIML	5	1.8	5	0.8	0	0.4
RSP	5	1.2	5	0.5	0	0.3
IND	43	4.7	72	4.46	106	5.6
Total	2691	100	2970	100	3209	100

Source: Based on Statistical Report in West Bengal Panchayat Elections from 2008 to 2018. West Bengal State Election Commission, Kolkata

Table-1 shows the TMC won 809 out of 2691 seats in the 2008 Panchayat election, with a vote percentage of 30.22. It gained 1384 seats out of 2970 in the 2013 election. It shows the increasing tendencies as 1595 seats were positively secured out of 3209 in the 2018 election. It achieved a vote percentage of 44.79 in this election. Compared with the 2013 Panchayat election, AITMC's party performances have improved regarding seats and vote share from 2008 to 2018. With this outcome, Trinamool Congress and Left political organizations dominated most of the political spaces in the Nadia district up to the 2013 Panchayat election. With the widespread criticism of the Leftist government, particularly in light of the Nandigram and Singur crises, the Trinamool Congress established itself in the Nadia district. Later, state politics viewed Mamata Banerjee as an influential leader in the state. In the struggle of Mamata Banerjee against the left, she proved herself to be the true alternative to the opposing voice. She was the only opposition leader who relentlessly opposed the left, which yielded her electoral benefit. Muslims constitute about 23 percent of the votes. Their votes are decisive, constituting 30 percent of the seats in the Nadia district. Trinamool Congress Government gives a monthly stipend of 2500 imams and muezzins. It distributed bicycles to girl students enrolled in madrassas. Provided scholarships for minority students.

Trinamool Congress offered reservations to Muslim OBC and declared Urdu the second language in the Muslim-populated district. Trinamool Congress intact Muslim voters due to the factors mentioned above that gave Trinamool Congress massive electoral victory in the Panchayat elections. The numerous welfare policies initiated by Mamata Banerjee, like the Rupashree Scheme, Kanyashree Scheme, Sabuj Sathi Scheme, Khadya Sathi Scheme, Swasthya Sathi, Imam Bhata, Pandit Bhata, etc., are the most popular schemes that influenced the voters and culminated in the resulting outcome of 2008, 2013 and 2018 Panchayat elections. **Table-**1 shows the 2008 Panchayat election; BJP won 205 out of 2691 seats with a vote percentage of 7.14. It got 385 out of 2970 seats, with a vote percentage of 13.14 percent in the 2013 election, and 759 out of 3209 seats in the 2018 election, with a vote percentage 26.7. In the 2008 Panchayat elections, the Bhartiya Janata Party did not have a significant impact. However, in 2008, left-wing organizations had more influence over a wider range of voters. The Trinamool Congress and the Left Front even balanced the 2013 Panchayat elections. It implies that the Bhartiya Janata Party's arrival strongly impacted the Panchayat elections in the Nadia district in 2013 and 2018. It means that the iconized political spaces have transformed with Narendra Modi's ascent to the position of a national populist leader. In these Panchayat elections, there were considerable differences between the seat and vote shares.

Compared to the 2013 Panchayat election in West Bengal's Nadia district, the BJP's party performance in the 2018 Panchayat election improved in terms of vote and seat share. The charismatic leadership of Narendra Modi, given his Gujarati roots belt, was largely nurtured through dedicated work as a skillful state leader. Hindu voters were not only institutionalized in saffron ideology and remained electorally loyal to Modi but also became the torchbearers of his novel brand of right-wing Hindutva politics. Saffron color comprises three political components: charismatic leadership, the strength of electoral rhetoric, and a vision of transformational governance. This pattern of party performances demonstrates the Trinamool Congress and BJP's intense electoral competition. The BJP has slightly benefited from capturing seats in the Blocks with more Hindu voters. This electoral situation highlights that CPIM, formerly the dominant force in state politics, has a lower voting percentage and likely switched to BJP. In recent elections, votes may have shifted more due to historical conflicts between BJP and AITMC officials and volunteers. The claim is that CPIM has weakened its ideological grip, and its traditional supporters have switched to another political party. The most likely explanation for this phenomenon falls into two categories. First, the CPIM voters have been split into two groups, and they now want the BJP to spread a negative message about the Mamata-led AITMC. Iconized politics, sentiment-based mobilization, and populist politics are other strong factors for the BJP.

The welfare policies that Modi has introduced include Jan Dhan Yojana, one of the largest financial schemes in the world, which opens bank accounts for 30 crore unbanked households, and Kisan Yojana, a direct income support program for the farming community. Awas Yojana, which offered to house 1.5 crore low-income people; Pradhan Mantri Ujjwala Yojana, which installed smoke-free kitchens in 70 million homes; and Swachh Bharat Abhiyan (Clean Bharat), which provided toilets to nearly ten crore people, were other significant programs (Heath & Tillin 2018). Gujarati Model and Narendra Modi's charismatic leadership is important in mobilizing ground-level leaders and voters. Hindu voters stayed electorally loyal to Modi, institutionalized the saffron ideology, and took up the mantle of his innovative form of right-wing Hindutva politics (Dasgupta 2020). The BJP criticized the Trinamool Congress for allegedly favoring Muslims. 'Nation First, national security, zero-tolerance approach to terrorism, the welfare of soldiers, battling infiltration, implementing the Citizenship (Amendment) Bill, combating left-wing extremism, Ram Mandir, Jammu & Kashmir - Article 370' were some of the key themes of Modi's populist campaign. **Table-**1 shows that in the Panchayat

elections of 2008, CPIM won 891 out of 2691 seats, with a vote percentage of 28.22; in the elections of 2013, it got 547 out of 2970, with a vote percentage of 22.16; and in the election of 2018, it occupied the 340 out of 3209 seats having vote percentage of 16.2. Compared to the 2008 Panchayat election in Nadia district, there is a declining pattern of party performance for CPIM in the 2013 and 2018 Panchayat elections regarding vote share and seat share. The CPI(M) cultivates a powerful organization with a broad network to keep a firm hold on the cadres and voters. As a result, Chief Minister Buddhadeb Bhattacharya created the new slogan, "Agriculture is our base, industry our future" (Jaffrelot & Verniers 2020). After acquiring agricultural plots from small farmers and landowners, he zipped across the state, setting the cornerstones for new townships, food parks, industrial units, shopping malls, and catering training facilities. The Left Front Government in West Bengal had created a positive and healthy environment in the industrial sector. The electoral success of the Left Front cannot be explained by economic parameters alone. The fact that the CPIM is a disciplined political party should be kept in mind in understanding the dynamics of power relations in West Bengal. Party discipline facilitates a strong link between the party leadership and the cadres.

This enables the leadership to translate effective organizational goals into grassroots action. The active involvement of the party cadres in the people's everyday life gives the CPIM strategic advantages in election campaigns. In the urban areas, the party maintains mass contact through the local committees and 'Mahila Samiti (Ghosh 2022). The Panchayati Raj revolutionized rural Bengal's economy and created a significant market for industrial goods during the Left regime in the state. The favorable industrial environment strengthened the Left Front Government. It triumphed in the 2008 Panchayat elections. Rising voter unhappiness with local incumbents on corruption, health, education provision, and other local public goods like roads and irrigation are examples of Left Front governance failures. Other programs include private benefit schemes like the Mahatma Gandhi program for drinking water, ration cards, bank loans, agricultural micro kits, old-age pensions, and the Indira Awas Yojana. Failures of state-wide programs, such as the stagnation of employment in rural areas, the inability to contain inflation, and issues with the Left Front's land acquisition practices close to Singur and Nandigram, might be attributed to non-local leaders. All of these problems, taken together, impacted the performance of the left front in the 2013 and 2018 Panchayat elections (Nath & Ray, 2022). The absence of left political force in the state and among the rural masses projects the historical visualization of its emergence in 1977.

Left Front government emerged, riding the wave of anti-Congress mass resentment. In the initial years, it undertook some popular measures like distributing vested lands among the landless, registering the names of the sharecroppers under Operation Barga, and reviving the Panchayati Raj institutions. At the same time, these democratic reforms helped consolidate the new communist party in the rural areas. However, undemocratic measures were followed later to eliminate opposition forces from the countryside. CPIM Neglected the voice of opposition to devalue and suppress the inherent identity forces that led to the decay of left rule even in the rural areas of West Bengal. In this regard, the Left Front rule that systematically and meticulously tried to direct consolidation as a dominating single party, even at the expense of all opposition parties, even junior partners, particularly in rural Bengal, has become irrelevant in electoral mobilization. **Table-**1 shows that in the 2008 Panchayat election, INC won 650 out. During the 2013 elections, INC won 515 out of 2970 seats with a vote percentage of 13.12; in the 2018 election, it won 379 out of 3209 seats with a vote percentage of 3.61. Comparing the 2008 Panchayat election in the Nadia district to the 2018 Panchayat election, there is a declining pattern of INC party performance regarding vote share and seat share. As a result, the INC party's performance has suffered as voters from the upper caste, Dalits, and Muslims have stopped supporting it. The majority of those who vote for Congress are from socially and economically disadvantaged groups. However, AITMC, which speaks directly to these communities, poses a real threat to Congress in the race for their votes.

The identity of the Dalit was historically less politicized. CPIM and Congress both had mileage in the reserved category voting performance, according to behaviors drawn from past electoral behavior of electorates in the Nadia district of West Bengal. It is because voting behavior's class-based orientation overshadowed caste-based mobilization or politics of identities. However, the recent Panchayat elections in 2018 showed the emergence of caste-based identity politics, as the BJP chose a Dalit as its state president. The Nadia district has been using the state president's identity. However, the deterioration of left politics in the state and rural West Bengal also destroyed the ideological essence of West Bengal politics. The ways of electoral mobilization consequently transformed into a pragmatic turn. The issues of labor and class identity-based mobilization are deformed into religion, caste, and identity politics. The features of national identity and issues and national tendencies overshadowed the regional identity of place and local social questions. The instrumental agencies like media and populism drastically shaped the authentic

political voices of rural society. The politics in West Bengal observed a drastic change and transformation from the Left-based political constructs to the emergence of Trinamool as a powerful political voice in the state. The changing demography and political situations are the vital cause of this transformation. Rising population growth, demographic fragmentation, middle-class dissatisfaction, and social and economic detachment are the general factors in the change of political regime.

Caste and Voting

The caste system largely affects the electoral campaign in rural areas, where caste and Baradari (Kinship) loyalty is seen as one of the most decisive factors determining the voting behavior of the villagers (Bandyopadhyay, 2012). In the Nadia district, individuals simultaneously hold multiple ethnic identities of language, religion, politicized umbrella caste categories (such as Upper Castes, Backward Castes, and Scheduled Castes), and highly localized sub-caste/kinship groups biradari or jati. Ethnicity matters in voting behavior and depends on the differences in the economic well-being of ethnic groups in a system (**Table-**2). When some ethnic groups are wealthy and others are poor, the silence of ethnicity in politics should increase. BJP's propaganda invites all majority community members to look at themselves as Hindu first and members of some caste groups second because of the socio-economic differentiation in the society. In a caste group, the richer people were more pro-BJP; they tended to be because of caste and class (mainly because of the party's reservations vis-à-vis caste-based quotas). It is still valid, but some changes have occurred in the context of post-1991 liberalization. Respondents believe Trinamool Congress got full majority support from the minority community (**Table-**2).

Table-2: Caste and Voting Preference of Respondents

Category	Voting Preference of the Political Party (%)			
	AITMC	BJP	Left	Others
General	35	40	20	5
OBC	40	35	18	7
SC	35	45	15	5
ST	30	50	15	5
Minority	82	3	10	5

Source: Field Survey, 2020-21

Factors Influencing Voting Behavior

A number of factors influence an individual's voting behavior. It is mainly determined by race, religion, caste, community, region, language, charismatic leadership, ideology, local issues, political wave, etc. Thus, an attempt has been made to determine the sources of voting behavior (**Table-**3).

Table-3: Distribution of Respondents According to Factors Influencing Voting Behaviour

Factors affecting Voting Behaviour	Number of Respondents	Percentage
The ideology of the Party	100	12.7
Programmes and Policies of the Party	160	15.88
Personality of the Candidate	140	7.94
Religious Consciousness	400	22.22
Caste Consciousness	250	17.46
Local issues of Electricity, Road, and Water	140	15.87
Any Other	10	7.93
Total	1200	100

Source: Field Survey, 2020-21

The reason is that Muslims see the BJP as a party threatening their interests. BJP has successfully increased its popularity among SC/ST community voters with the help of pro-poor policies like the Ujjala Yojana, Pradhan Mantri Awas Yojana, Swatch Bharat Mission free toilet, Free Ration, and CAA/NRC Issues. **Table-**3 displays that the majority of respondents, i.e., 22.22%, gave importance to 'religious consciousnesses in deciding on whom to vote for in the election, while 17.46% of respondents emphasized caste consciousness and 19.20% of respondents emphasized 'local issues of electricity, road, and water of electricity. Other factors viz., 'programs and policies of the party,' 'ideology of the party had received preference of the electorates at the rate of 12.70%. It shows that religion and caste is the most important factor in voting behavior in Nadia district voters. The candidate's personality has minimal influence on the voting decisions of the region's people. Apart from these factors, priority has also been given to other factors like political parties' leadership and their representative's work or performance while voting. Therefore, it is essential to study the voters' preferences regarding political parties' leadership and their representative's work. Considering that the respondents' questions were asked, their opinions are classified below.

Conclusion

Trinamool Congress is becoming increasingly popular in Nadia district, West Bengal. BJP's political performance is a little better where the proportions of Hindu and Matua populations are high. It is a party with a strong ideological foundation that may appeal to the masses of one particular religion. On the other hand, the mutual political rivalries between CPIM and Trinamool congress voters also caused the massive success of the BJP in the Nadia district. The traditional vote banks of CPIM have also transformed their vote and support in favor of the BJP to degrade Trinamool, which has covered the voting scale in the political space of West Bengal. The leadership's quality is still a factor for the Muslim electorate. In regions where Muslims predominate, all major political parties often choose a Muslim as their candidate. They support those parties that promise them more security, respect, and identity. It provides them structurally a wide range of protection. CPIM and AITMC use Muslims as an electoral support base in their respective era of influence. Strategically, both parties succeeded in creating fear and threat of the BJP and rising communalization in the state. Although caste, class, and religion are significant factors in elections and maintaining strong control over people's perceptions. It functioned by identities in general and caste politics in particular. In the Nadia District, these imagined identity variables are particularly crucial and visible in electoral behavior and mobilization in the rural Nadia district. The CPIM has sustained its pro-poor policies for a longer duration. Its policies always benefited the scheduled castes, the Scheduled tribes, and the Muslims in Nadia district, West Bengal. It provided CPIM the power hold for the long term. So, the result revealed that the Trinamool Congress has the more prominent mass acceptance in the Nadia district Panchayat elections. Consequently, an electoral pattern indicates the ideological shifting in order from Left to Centre and now emerging trends of right in the Nadia district.

The politics in West Bengal observed a drastic change and transformation from the Left-based political constructs to the emergence of Trinamool as a significant political voice in the state. The changing demography and political situations are the vital cause of this transformation. Rising population growth, demographic fragmentation, middle-class dissatisfaction, social and economic detachment are the general factors in the political regime change. The emergence of the new middle class in the West Bengal demographic scene caused the degradation of voting influences of left parties. Remarkably, the left's support base was diminished with a long-time sustained problem, including a lack of industry, job opportunities,

and declining health and educational systems in the state. Overall, the civic memories and rise of Mamta Banerjee at a populist scale further challenged the CPIM space among the common masses. The left found the issue of land acquisition in Singur and Nandigram too expensive. In the Nadia district of West Bengal, Most SCs and STs voted for the left until it benefitted their caste interests. The left's policies, such as Land Reform and Panchayati Raj, offered the lower castes a sense of social advancement. It gave them political power at the local level and protected them from the powerful upper-caste landowner class. As a result, the left continued to get support up to the 2008 Panchayat elections. Even after the thirty years of rule by the left parties, the caste and religious consciousness was inherently located among the mindset of electorates. The religious sentiment of social groups was not changed into class consciousness. Economic diversification was not achieved, and the left regime did not address unemployment issues. The socio-economic backwardness of religious minorities projected the inter-ethnic, inter-community gap that leads to the degeneration of left politics. It seemed that the populist movement of TMC and the political iconization of Mamata Banerjee provided a sense of hope among the long-term subjugated social groups. Therefore, it benefitted the TMC in electoral victory.

The numerous welfare policies initiated by Modi, often based on earlier Congress planning, including Jan Dhan Yojana, one of the biggest financial schemes in the world, opening bank accounts for 30 crore uncovered households, and Kisan Yojana, a direct income support scheme for the farming community. Other mega programs were Awas Yojana, which provided housing to 1.5 crore poor people; Pradhan Mantri Ujjwala Yojana, which created smoke-free kitchens for 70 crore families; Swachh Bharat Abhiyan (Clean Bharat) and provided toilets to around ten crore people. The BJP criticized the Trinamool Congress for allegedly favoring Muslims. 'Nation First, national security, zero-tolerance approach to terrorism, the welfare of soldiers, battling infiltration, implementing the Citizenship (Amendment) Bill, combating left-wing extremism, Ram Mandir, Jammu & Kashmir - Article 370' were some of the key themes of Modi's populist campaign. Communalism plays a determining role in the electoral politics in Nadia district, West Bengal. Political parties and politicians use the communal division in population as the primary card during elections. As a result, the voters of the Nadia district very often vote based on religious considerations and local problems and issues.

However, the trend is changing slowly yet gradually. The sign of such consciousness is reflected in the voters' opinion regarding the most crucial issue

in the 2018 Panchayat election. However, there are visible signs that Bengal electorates are maturing, and the election is becoming more competitive. Nadia district is also no exception to that. Maybe in the coming days, communalism in politics may not remain a solid card to win regional elections. It is changing the course of electoral politics in the Nadia district. An electoral pattern indicates the ideological shift from Left to Centre and now emerging right-wing trends in the Nadia district electoral politics.

ASSESSMENT OF RURAL TOURISM DEVELOPMENT IN KALIMPONG DISTRICT, WEST BENGAL, INDIA

Amita Halder and Sanjay Kumar

Abstract

Rural Tourism is understanding and going through the rural lifestyle, nature-based activities, natural products or it could be a modified form of ecotourism. In India it is growing in a vast scale. This paper aims to provide a holistic view of rural tourism sites and the success factors for the development of rural tourism in Kalimpong district, West Bengal. Based on an empirical study with the help of secondary data sources and observation of field study. A qualitative method is used to review the current scenario of the rural tourism sites in Kalimpong District. A SWOT analysis method is also used to identify success factors working behind developed rural tourism in the study area. The study highlights, Kalimpong district as a popular rural tourism destination and recognized the strength, weaknesses, opportunities, and threats of rural tourism in the study area.

Introduction

To enhance and sustain the quality of rural life, tourism is one of the essential sector and act as contributor. Rural tourism (RT), not a new concept for World (Gao & Wu, 2017; Roslina, Dupre & Wang, 2021) but this trend has emerged from last ten years in India. Rural tourism evolved in mid 70s in developed countries (Lane, 1994; Verma and Jain, 2018; Duha, 2021), its interest raised among people in the second half of the 20th century and became a useful tool for the development of rural areas (Duha, 2021). Indeed, globalization and urbanization have had a significant impact on the international, national, and regional tourism industries, leading to increased priority and profitability in many cases (Lane, 1994; Duha, 2021). This combines rural amenities and activities to offer visitors an authentic and enriching experience in rural areas (Fleischer and Tchetchik, 2005; Gartner, 2005). According to the United Nations of World Tourism Organization (2017), this form of tourism focuses on providing tourists with a deeper connection to the countryside (remote or rural areas), local culture, and traditional ways of life and characterize on the basis of population density and settlement size,

land use and economy, and traditional social structure (Lane, 1994). This provides tourist relax from their busy schedule with pollution-free environment, fresh air, open-wide space, connecting with nature, and going back to their roots i.e. far away from the city (Irshad, 2010;). It has many subsets like agri-tourism, cultural tourism, homestay tourism, eco-tourism, etc. (Irshad, 2010; Fleischer and Tchetchik, 2005; Ashtani, 2005). According to the Ministry of Tourism of India (2022), rural tourism is working as an integrated model, because it took account of various resources like cultural, Social, economic, and environmental aspects and the role of the stakeholders (Cawley & Gillmar, 2007). Indian government had indeed been promoting rural tourism as a means of sustainable development in rural areas so that people can become self-reliant or Atma-Nirbhar. It is an effective tool to eradicate poverty, increase the quality of life of local people, development of remote areas (Roberts & Mitchell, 1998). In today's world homestay business is a perfect option for rural tourism and indeed a component of the broader tourism and hospitality industry, and it shares some key characteristics with other service-based businesses within this sector. Rural homestay is an important part; because without staying with local people, tourists cannot participate actively in rural activities. Facilities like accommodation, food, beverages, Products, and infrastructures are taken into consideration to develop rural tourism. Rural tourism gives new rise in generating employment and income, entrepreneurship, and empowering local people and women (Das, 2021). It is also preventing the out-migration of youth from rural areas. Rural tourism not only gives work opportunities but also promotes the environmental, economic, and socio-cultural sustainability of rural areas.

Study Region

Kalimpong district was selected for this research work, as its 21st district of West Bengal in 2017 carved out from the Darjeeling district. The district extents from 26°51'N and 27°12'N latitude and 88°28'E and 88°53' E longitude. The district has consisted of three community development blocks and shares boundary with Sikkim, and Bhutan. It is famous for Orchids and known as the "Land of Orchids". Kalimpong has hilly areas, natural beauty, picturesque villages, river valleys, culture, heritage, etc. It is observed in (**Table-**1) that this district comes under rural areas, bounded by forests, and diversities of flora and fauna. The main source of economy and livelihood is agriculture. There are many variations in agriculture. Cash crops (Ginger, Large Cardamom), Plantation crops (Tea, Medical plants, Cinchona, Pineapples), Horticulture (Orange), floriculture, and Orchid culture are also the attractions of this region.

Kalimpong is recognized as a natural greenhouse region (Sharma & Mandal, 2020), traditionally different from other districts of West Bengal and inhabited by ethnic groups (**Table-**1).

Table- 1: General Information on Kalimpong District to Develop Rural Tourism.

Attributes	C. D Blocks of Kalimpong District		
	Kalimpong I	Kalimpong II	Gorubathan
Total Population	74746	60663	66830
Area (Sq.km)	360.40	241.26	442.72
Density (Sq.km)	210	280	140
Number of households	15358	13172	12662
Rural Areas	Mostly rural areas except one census town Kalimpong	Consist only rural areas	Consist only rural areas
Forest area	Forest area is 52% of the total district		
Bio-diversity	This region comes under eastern Himalayas. It is rich with different types of flora and fauna i.e. Mammals - 90species, Orchids - 300 species Birds- 550 species.		
Economy	Mainly depend on agriculture. About 80% people of this district associated with farming for their livelihood.		
Agricultural Landuse under Cultivate (Percentage)	37.19	34.5	44.17
Variation of Agriculture	Subsistence farming, Cash crop raising, Plantation farming, Horticulture, Floriculture, Orchid culture, Sericulture		
Accommodation for tourist	Homestays		
Tradition	Society is traditional because of inhabited by ethnic people like Gorkha, Lepcha, Bhutia, Etc. Religions are Buddhist, Hindu, Christian, Islam		
Small scale industries	Handicrafts, Agro-based products, Homestay		

Source: District census handbook of Darjeeling (2011)

It is one of the most popular tourist destinations among other destinations of West Bengal, but comparatively is a latecomer on the tourist map. It is attractive for its landscapes, pleasant weather, and richness of biodiversity, ethnic culture, historical heritage, handicrafts, and panoramic view of Mount Kanchenjunga. In current times, tourists prefer niche types of tourism, in which locations are off-beat destinations, rather than known tourist places. This year, eight villages from Kalimpong district have been nominated for the annual "Best Tourism Villages" by UNWTO.

Objectives

The major objective of the present study is to review the current scenario of rural tourism sites and to identify key to success factors of rural tourism in Kalimpong district.

Database and Methodology

For the study, both primary and secondary data have been used. Primary data was gathered from personal observations and interactions with local people and homestay owners and online with local. Secondary data have been collected from relevant documents of published research papers, reports, and books. This dataset include- District census handbook of Darjeeling (2011), Kalimpong the Nest of smile (2018), Kalimpong Calling (2019), document on Homestays of Kalimpong (2022), and Homestays of Kalimpong (2023) published by District Magistrate of Kalimpong, West Bengal Homestay Tourism Policy (2022) published by Government of West Bengal, District survey report of Kalimpong (2022) etc. Reports and books are published by the district administration of Kalimpong. Schemes and policies-related documents published by West Bengal Government in 2022. All these are used to meet the objectives of the study. Based on the primary and secondary data, a SWOT (Strength, weakness, opportunities and threat) analysis has been done to identify key success factors for rural tourism development in the study area. SWOT analysis is a Conceptual Framework (**Fig. 1**) for identifying and analyzing an organization's strengths, weaknesses, opportunities and threats. Strength characterizes business as competitive advantage over others; Weakness characterize business as disadvantage relative to its competitors; Opportunities elements in the external environment that allows it to formulate & implement growth strategies; Threats elements in the external environment that can endanger the business and its ability to operate. The primary goal of SWOT analysis is to increase awareness of the factors that go into making a business decision or establishing a business strategy.

Result and Discussion

The current scenario of rural tourism sites in Kalimpong District

Kalimpong District is a hill station covered with reserve forests, river valleys, and foothills of the Himalayan region. Its elevation varies from 131 meters to 3163 meters (**Fig.** 2). Out of the total population in Kalimpong, 9.1% of people live in urban areas, while 90.9% of people live in rural areas (Census, 2011). People in rural areas are connected with agriculture with vast area of floriculture and agrarian resources and a few tea gardens along the southern Tarai and Dooars region of Gorubathan block (Podder, 2020). Most of the villages of three blocks of Kalimpong district are inhabited by ethnic people like Tamag and Lepcha. Based on natural and human resources, rural tourism has been growing in different villages of Kalimpong District since 2011-2012 (Sharma & Chettri, 2023, Das, 2021). Mostly tourism sites have been developing in remote villages within the forest and hilly tracts in the Kalimpong region (Das, 2021). Every three blocks of Kalimpong have rural tourism sites, from them some are very popular destinations and others are little known.

Kalimpong-II has the greatest number of rural tourism destinations because it comes under the old silk route circuit, which is connected to Sikkim. Homestays are one of the key factors to develop rural tourism in this area, which varies from 1015 meters to 3163 meters. In Kalimpong I and Gorubathan block, rural tourism sites have been developed at middle altitudes (1015 meters to 2024 meters) and nearby roads and rivers. Kalimpong I mostly come under urban areas. So, here new rural tourism sites are now developing like Chuikhim, and Nimbong. Gorubathan block comes under in Dooars region and due to accessibility hotels are grown up, that's the reason homestays are not more developed here. These rural tourism sites are also known as eco-tourism villages. These are Ramdhura, Sillary Gaon, Ecche Gaon, Rikisum, Loly gaon, Chuikhim, Kagey, Jhandi etc. These villages are picturesque, lush green trees, traditional homes, hills side cultivation, home of Orchids and different flowers, cinchona plantation, tea gardens, and majestic views of Kanchenjunga and hospitality of local people.

Strength

In the study area, under strength mainly 5 factors identified based on literature review and observations, which the potential resources are playing important role in the success of rural tourism (**Fig.** 2 and 3).

The factors are identified by using SWOT (Strength, Weakness, Opportunities, and Threats) analysis. Strength and Weakness are considered as internal factors i.e. activities involved in these factors are controllable and can be changed like location, team, intellectual properties etc. And on the other hand, Opportunities and Threat are external factors i.e. activities involved in these factors cannot be changed as under opportunities advantage can be taken but under threat only precautionary measures are taken. Ex. competitors, prices and customers (**Fig.** 3).

Historical

Natural: Natural resources are the Potential component to the development of rural tourism in the Kalimpong District (**Table-**3). The unique mountainous topography, river valleys, mesmerizing weather, majestic view of Mount Kanchenjunga, Night view of various cities from the hill region, diversities of flora and fauna, picturesquare villages and lush green trees and forest of pine and Oak, tea garden attracts a huge number of domestic and foreign tourist (Das, 2021: Bhutia, 2014: Khan and Mitra, 2017: Bhattacharya et. al, 2014). These are the key reasons for the successful development of rural tourism in Kalimpong district, Darjeeling Himalayan region.

Cultural

In rural tourism, tourist gains experiences from the local art, culture, and lifestyle of local people (Bhutia, 2014). Kalimpong is a full variation of traditional art, culture, communities, and religions. Because of the trade route to Tibet, this is earlier known as the old silk route passed through Kalimpong. In this region, various types of tribal people inhabited like the Rai, Damis, Limbus, Gurungs, Bhutia, Sanki, Sherpa, Khas, Yolmo, Magar, Newars, Tamangs, Bhujel, Kami, Lepcha, etc. The Lepchas are the original indigenous tribes in the study area. Each of these people is very unique in their culture, religion, and heritage. Most people practice Hinduism, followed by Buddhism, Christianity, and Islam. Their main languages are Nepali, Hindi, Bengali, and English. Here, Hinduism is pre-dominated, but Buddhist and Christian culture is also an attraction of this region. There are so many popular monasteries, temples, and churches (tab no. 3) in the three blocks of Kalimpong District. Kalimpong is also known for its traditional handicrafts, wood carvings, embroidered items, bags & purses with tapestry work, copperware, and Tibetan jewellry. Cuisine: In Kalimpong district, another attraction is delightful ethnic cuisine like Momo, Gundruk, Ko Jhol, Thukpa, Kinema KO Jhol, Sel Roti, Aalu Dum, and Ningroo with Churpi (One Kind of Cheese), Shya Phaley, etc.

This region is also renowned for cheese, noodles, and lollipops. Organic Vegetables and homely food of local people are preferred by tourists. It changes the taste buds of tourists and attracts tourists to rural tourism. Fair and Festivals: The people have come from different ethnic groups. There are so many fairs and festivals celebrated with great joy like Christmas, Diwali, Dusshera, and Losar. A large fair is held at Beni (the Confluence point of river Teesta and Rungeet) on the 14th of January every year. They are celebrated their fair and festivals with traditional dance and music like ghatu dance, dhan, damphu, Kaura, Maruni etc.

Historical

Kalimpong has its unique history. Firstly, Kalimpong was ruled by Sikkim still 1706 when Bhutan invaded Sikkim (Podder, 2020). Then it was acquired by the British and established colonial rule. Kalimpong is connected with Tibet, Nepal, and Bhutan by trading and sharing the national and international border. That's the reason many ethnic cultures mixed over. Donzong kingdom of Sikkim and British ruled over Kalimpong. They left their culture, Architecture (tab. no. 3) and artifacts like Tibetan style, Scottish, Roman, etc. In 1947 Kalimpong become a part of West Bengal (**Table-**2).

Accommodation

In Kalimpong region, tourism developed in the remote areas, which have natural landscapes, and pollution-free, fresh air. Rural tourism has been implemented in the various villages from three community block of Kalimpong district. The Sites are known as the off-beat destination of rural tourism for their crowded and hassle-free environment from urban areas. Rural Homestays are playing a vital role in rural tourism (Ministry of Tourism, 2023). Here, Homestays are the main accommodation and one of the attractions for tourists in rural tourism in this area. Homestay is an affordable alternative accommodation for tourists (Sharma & Chettri, 2023; Kumaran et. al, 2019). Where tourists are staying with local families, thus enabling them to gain knowledge and experience the culture, cuisine, and lifestyle of local people (Ministry of Tourism, 2023). Also, tourists are welcomed and can experience the traditional hospitality of the host family and the local community. It gives a unique and gracious feel to the tourist. In Kalimpong District, Homestays are a growing phenomenon in rural tourism in the study area (Das, 2021). In 2022,

there were 402 registered homestays in the three blocks of Kalimpong district. Now, it has increased to 1009 in 2023. It has increased significantly around 60% within one year. Mostly Homestays are concentrated in the Kalimpong II block (73%), followed by Kalimpong I block (20%) and Gorubathan block (7%). Kalimpong-II block is highest in the growth of Homestays than the other two blocks (**Fig.** 4). Because of some factors are working in this area like high altitude, conducive climate, large forest area, organic farming and silk route region, etc.

Activities

Kalimpong District has mostly hilly areas except for the South-eastern part of Gorubathan block. The people are associated with agriculture and the nature of this region. They are transforming their traditional agriculture, and nature-based knowledge into tourism activities. These activities are trekking, hiking, camping, river rafting, walk-in Jungle, identifying the plants and organic farming and harvesting, local festivals, nature photography, Mount biking and cycling, and bird watching. The Neora Valley National Park and forest are known as the "Paradise of Birds" in Kalimpong block II. The villagers in a group or individual are working as a guide. These activities keep engaging tourists with the local people.

Organic Farming

Kalimpong district has potential in organic farming and agro-horticulture for its temperate climate. According to Census (2011), more than 80% of people in Kalimpong depend on farming to manage their livelihood. The district is producing paddy, maize, millets, pulses, oilseed, and potatoes in small amounts, and medicinal plant varieties with the help of organic cultivation (Bhattacharya et. al, 2014). But it is widely known as one of the leading producers of large amounts of cardamom, flowers, and various cash crops like ginger, betel-nut, oranges, organic tea, Dalle Khursani (small chilies), and Mulberry Seri-culture (Chakraborty, 2023; Ram and Maji, 2018). The tribal people of Kalimpong like Lepcha, Bhutia, Rai, etc have utilize their family members as agriculture labour and using local resources, through traditional knowledge and methods for organic farming (Patel and Lepcha, 2023). These methods are more environments friendly (Biswas et. al., 2011). Over time period organic farming has been growing interest among tourists. It's become an opportunity for villagers and a success factor of rural tourism. Various villagers (rural tourism sites) of Kalimpong district, offers tourist to stay in farm-stay and homestay to gain knowledge of organic farming and the livelihood of local people.

Government Policies

Government policies are an important factor to develop rural regions through rural tourism. The entire stakeholders, who are related to tourism activities is bounded by local government and state government regulates. The government of West Bengal has taken many initiatives to growth of rural tourism through creating alternative income generate, employment, business opportunities, and community development. Rural homestay is an integral part of rural tourism. To promote homestay and increase local entrepreneurship, the state government gives the incentives of 1.5 lac rupees to each eligible homestay owner to achieve and maintain basic standards of homestay. Also gives subsidies on electricity and homestay businesses. No commercial taxes are levied on homestay owners, who have not more than 6 rooms (**Fig. 4**).
